SYMPOSIUM ORGANISERS

The Ceylon Institute of Builders (CIOB), Sri Lanka

Established in 1961, the Ceylon Institute of Builders (CIOB) is the premier institute for Building Professionals in Sri Lanka with a strong network of Engineers, Architects, Surveyors and similar allied professions who work to inspire, encourage, educate and train students, builders, and professionals in the country. The institute welcomes young entrants and mature professionals with or without a background in construction to achieve professional level careers in the country. They are provided with a well-structured development programme that eventually leading to gaining corporate membership of the institute.

http://www.ciob.lk/

Department of Building Economics University of Moratuwa, Sri Lanka

The Department of Building Economics, University of Moratuwa, Sri Lanka was founded in 1983. It is currently the pioneer Sri Lankan institution to offer programmes in Quantity Surveying, Facilities Management, Project Management, Construction Law and Dispute Resolution and Occupational Safety and Health Management. Building Economics and Management Research Unit (BEMRU) is the research arm of the Department of Building Economics, which specialises in research in Building Economics and Management in the country as well as internationally.

ASSOCIATE PARTNERS

Centre for Smart Modern Construction, Western Sydney University, Australia

Western Sydney University is a world-class university with a growing international reach and reputation for academic excellence and impact-driven research. It is ranked amongst the top three percent of universities in the world, globally focused, research-led and committed to making a positive impact – at a regional, national and international level. It was established as a modern university in 1989 from its predecessors dating back to 1891. The WSU currently has over 40,000 students in a sprawling series of campuses across the Western Sydney region.

https://www.westernsydney.edu.au/

The University of Newcastle, Australia

The University of Newcastle, Australia, established in 1965, is a leading public university with campuses across Newcastle, the Central Coast, Port Macquarie, and Sydney. Offering a wide range of undergraduate, postgraduate, and research programs spanning diverse disciplines such as Arts, Business, Engineering, Health Sciences, and Environmental Studies, the university is committed to academic excellence, research innovation, and community engagement, preparing students for successful careers and meaningful contributions to society. With a strong emphasis on interdisciplinary collaboration and industry partnerships, the University of Newcastle ensures students gain practical experience and skills relevant to today's workforce.

https://www.newcastle.edu.au/

Built Environment Project and Asset Management (BEPAM)

Journal, Published by Emerald Group Publishing

BEPAM provides, a unique one-stop forum that publishes peer-reviewed research and innovative developments in both project management and asset / facilities management of building and civil engineering infrastructure. The journal also targets important interface issues between the planning, design and construction activities on the one hand, and the management of the resulting built assets / facilities on the other. Launched in 2011, BEPAM is well established internationally, e.g., being encouraged by CIB, recognised by the Australian Business Deans Council and indexed in SCOPUS, EBSCO, INSPEC and the Emerging Sources Citation Index (ESCI) of Thomas Reuters.

http://www.emeraldinsight.com/bepam.htm

ASSOCIATE PARTNERS

Colombo School of Construction Technology (CSCT), Sri Lanka

The CSCT was established in 2008, with the motto 'Sapientia et Doctrina', which is Latin for Wisdom and Learning. It strives to create a learning environment to nurture the development of critical thinking skills; support innovation; and develop knowledge and expertise of our students. CSCT faculty have expertise in a broad range of specialties and have developed curriculums in each of the programs that meet the needs of the construction industry.

https://csct.edu.lk/

Deakin University, Australia

Deakin University is a public university in Australia, with multiple campuses across Victoria and New South Wales. It was founded in 1974 and is named after Alfred Deakin, Australia's second Prime Minister. Deakin University offers undergraduate, postgraduate, and research courses across a wide range of disciplines, including Arts, Business and Law, Education, Engineering, Health, Information Technology, Science, and Sport.

https://www.deakin.edu.au/

Massey University, New Zealand

Massey University is a reputable institution of higher learning located in New Zealand that prides itself on academic leadership, research excellence, and innovative teaching grounded in real-world issues. The university offers a range of academic programs and services to support the academic and personal development of its students. The university offers postgraduate degrees that you can complete fully online and is the leading university in New Zealand for online and borderless education.

https://www.massey.ac.nz/

The University of Adelaide, Australia

The University of Adelaide is a well-regarded institution of higher learning and innovation located in Adelaide, Australia. It is a member of the prestigious Group of Eight, which consists of Australia's top research-intensive universities. The University of Adelaide has consistently received high ratings from respected international assessments, which is a testament to its commitment to academic excellence. It offers a range of undergraduate and graduate degree programs and has a strong emphasis on research. Students can choose from a variety of areas of study, including accounting and finance, agriculture, food and wine, allied health, animal and veterinary sciences, architecture, arts, biomedical science and biotechnology, and business. The university prides itself on being a future-maker for its state, nation, and the world. It has a strong commitment to creating meaningful change through contemporary educational and research excellence. The institution aims to meet the evolving needs of its local and global communities while applying proven values that celebrate its proud history.

https://www.adelaide.edu.au/

ASSOCIATE PARTNERS

Indian Institute of Technology Madras (IIT Madras), India

Indian Institute of Technology Madras is one among the foremost institutes of national importance in higher technological education, basic and applied research. The institute has sixteen academic departments and a few advanced research centres in various disciplines of engineering and pure sciences, with nearly 100 laboratories organized in unique pattern of functioning.

http://www.iitm.ac.in

Dr. Bhanuben Nanavati College of Architecture, India

Dr. Bhanuben Nanavati College of Architecture for Women (BNCA), located in Karve Nagar, Pune, is a premier institute affiliated with Savitribai Phule Pune University and part of the Maharshi Karve Stree Shikshan Sanstha. It offers undergraduate and postgraduate programs in architecture exclusively for women. The campus features advanced facilities, including India's first Fab-Lab in Digital Architecture with 3D printing, CNC machines, and robotic arms. BNCA also provides a well-stocked digital library, paperless LMS, modern studios, and fully equipped workshops. Hostel accommodation is available for over 1,200 students, with amenities like a gym, dining halls, and solar water heating. As a United Nations Academic Impact (UNAI) Hub, BNCA promotes global collaborations and holistic education, nurturing future-ready architects.

ACKNOWLEDGEMENT

We extend our sincere appreciation to the Ceylon Institute of Builders (CIOB) for inviting the Building Economics and Management Research Unit (BEMRU) of the Department of Building Economics, University of Moratuwa, to jointly organise the 13th World Construction Symposium (WCS) under the theme "*Sustainable Futures: Shaping a Regenerative Built Environment for Future Generations.*" This symposium marks the 13th milestone in the WCS series, which commenced in 2012 and has since been continued through the generous contributions and support of numerous individuals and organisations.

We gratefully acknowledge our Associate Partners: Western Sydney University, Australia; The University of Newcastle, Australia; Built Environment Project and Asset Management (BEPAM) Journal, published by Emerald Group Publishing; Colombo School of Construction Technology (CSCT), Sri Lanka; Deakin University, Australia; Massey University, New Zealand; The University of Adelaide, Australia; Indian Institute of Technology Madras (IIT Madras), India; and Dr. Bhanuben Nanavati College of Architecture, India.

We are especially thankful to all the authors who chose the 13th WCS as a platform to disseminate their research. Our heartfelt gratitude is also extended to the international and local scientific committee members for their rigorous reviews and constructive feedback, which ensured the high standard of accepted papers. We would like to further extend our gratitude to the chief guest, keynote speakers, panellists, session chairs, session coordinators, paper presenters, and other invitees, whose commitment and active participation greatly enriched the symposium. Their support enabled us to maintain the momentum of the annual WCS series, leading to its successful 13th iteration this year.

We also express our appreciation to the Editor-in-Chief of BEPAM and the team at Emerald Group Publishing for their collaboration, as well as to our sponsors, whose generous contributions made this year's event possible. Our gratitude is further extended to government and other institutions and all other supporting partners who provided assistance in various forms to make this symposium a success.

A special note of thanks goes to the panellists and moderators of the panel discussion on the theme "*2030 Step Ahead: Strategic Foresight for the Sri Lankan Construction Industry.*" The session brought together distinguished academics and industry leaders to discuss on sustainability-related challenges facing the Sri Lankan construction sector. The discussion emphasised the importance of strengthening collaboration between academia and industry, with key insights distilled into ten thematic summary areas that will guide the focus of the next World Construction Symposium.

Finally, we extend our heartfelt appreciation to our colleagues in the Organising Committee, the Symposium Secretariat, and the Department of Building Economics for their dedication and tireless efforts in ensuring the success of the 13th World Construction Symposium 2025.

Editors

The 13th World Construction Symposium
Colombo, Sri Lanka
August 2025

PREFACE

The 13th World Construction Symposium (WCS 2025), jointly organised by the Ceylon Institute of Builders (CIOB) and the Building Economics and Management Research Unit (BEMRU) of the Department of Building Economics, University of Moratuwa, was held on the 15th and 16th of August 2025. The symposium was organised in partnership with the Western Sydney University, Australia; The University of Newcastle, Australia; Built Environment Project and Asset Management (BEPAM) Journal, published by Emerald Group Publishing; Colombo School of Construction Technology (CSCT), Sri Lanka; Deakin University, Australia; Massey University, New Zealand; The University of Adelaide, Australia; Indian Institute of Technology Madras (IIT Madras), India; and Dr. Bhanuben Nanavati College of Architecture, India.

This year marks the 13th milestone in the WCS series, which has been held annually since its inception in 2012. Through its past iterations, the symposium has grown steadily, earning recognition among academics and industry professionals, both local and foreign, as a multi-stakeholder platform to share research, practical insights, and experiences within the built environment and construction domain. This year's symposium was convened under the theme *"Sustainable Futures: Shaping a Regenerative Built Environment for Future Generations,"* envisioning a path towards sustainability and resilience for the industry.

The symposium attracted over 120 full paper submissions, each undergoing a rigorous peer-review process as outlined below:

- All submitted full papers were reviewed by at least two independent reviewers from the symposium scientific committee through a double-blind process. Reviewers evaluated papers based on originality, significance, reliability, presentation quality, and relevance to the symposium's scope. Final decisions on acceptance or rejection were made by the Scientific Committee Co-chairs, who also serve as editors of the proceedings.
- At least one of the authors of all the accepted papers were required to register and orally present the paper in the symposium.

Following this process, 108 papers were accepted for publication. Notably, authors of the selected papers represented countries including Australia, India, Indonesia, Sri Lanka, South Africa, the United Kingdom, and the UAE. Collectively, the papers address a broad spectrum of topics across ten subthemes: sustainable construction methods and processes for future generations; sustainable, resilient, and regenerative buildings; products and materials for a circular and sustainable future; socio-economic and cultural dimensions of built environment sustainability; innovation and smart technologies for sustainable futures; decision-support systems and assessment frameworks for a sustainable built environment; retrofitting and reuse of buildings for sustainable futures; solutions for modernizing and refurbishing existing buildings and adaptive reuse of buildings; awareness, education, training, and policy interventions for sustainable futures; and Artificial Intelligence (AI) for a sustainable built environment.

As Scientific Committee Co-chairs, we are committed to upholding the highest standards of publication ethics and scholarly quality. Accordingly, the emphasis was placed on the rigour and relevance of accepted papers rather than their quantity. The proceedings presented here reflect the dedicated efforts of authors, reviewers, the organising committee, associate partners, and sponsors. It is our sincere hope that this body of work will contribute to advancing knowledge and inspire further dialogue as we collectively strive towards shaping a regenerative built environment for future generations.

SYMPOSIUM INFORMATION

IMPORTANT: To ensure the proper execution of WCS 2025 hybrid symposium, please pay special attention to the instructions below. If you have any questions or difficulties following the guidelines, please contact the WCS 2025 Secretariat (info@ciobwcs.com) who will be happy to help.

• How will WCS 2025 Hybrid Symposium Work?

The conference is delivered physically at Sir Lanka Foundation Institute, Colombo and virtually over a professional platform, Zoom, and is managed by a competent and experienced technical team.

All virtual paper presentations must be pre-recorded to improve the quality of the delivery, avoid going over time and avoid any technical issue. However, speakers **should be virtually present for their entire session** in order to answer questions and participate in the discussion.

The virtual conference is similar to any in-person conference. Presentations are assembled in parallel sessions according to themes. Participants can access the session of their choice by entering the WCS 2025 main meeting using the meeting ID and passcode and then selecting the breakout room for the parallel session of their choice. All registered attendees can attend all parallel sessions and switch from session to session at will.

The symposium inauguration, panel discussion and the sum-up are held in the WCS 2025 main meeting room.

As with in-person conferences, there will also be a dedicated period for questions and discussion after the presentations. Participants are able to use the chat or verbally ask questions during the Q&A session. The session chairperson may select a few questions, depending on the time allocated for the discussion, and read them to the presenter, who can answer verbally.

All sessions are fully recorded. Please note that we automatically assume that presenters accept their recorded presentation to be made available to participants for post-conference streaming. In case of refusal, presenters need to notify us at info@ciobwcs.com **before 14 August 2025** and the secretariat will manage the requests.

• Preparing for your Virtual Session - Instructions for Virtual Presenters:

Follow the instructions below when presenting your paper at WCS 2025 virtual symposium.

Before the symposium starts:

- Make sure that you have uploaded your pre-recorded presentation following the given instructions and have completed the registration process.
- Refer the Symposium Programme and the Session Plan to find your presentation in the symposium programme as scheduled.
- Make sure to install Zoom on your computer and update it to the latest version (version 5.3.0 or higher).
- In preparation for the meeting, you can join a test meeting via

https://support.zoom.us/hc/en-us/articles/115002262083-Joining-a-test-meeting. For the best experience, please use your webcam and test your audio.

- Test your internet speed, we recommend an Internet connection download speed of at least 1.5Mbps. You can test your download speed here.
- A microphone is recommended as well as a quiet place cut off from ambient noise for better interactions.

Before your session starts:

- Please make sure to join your assigned virtual session **10 minutes prior to the session start time** in case there are any issues that need to be worked out. Each session is conducted in a breakout room within the main Zoom meeting.
- When entering the session, make sure to identify yourself with your **name as it appears on your paper** to help the technical staff and the session chair to find you easily.
- Test your audio and video as you join; Mute your microphone when not speaking; Position your webcam at eye level and make eye contact as much as possible.

During the session:

- As with a physical meeting, each session will proceed in the order identified and maintain the schedule.
- Each parallel session comprises of the paper presentations (via playback of pre-recorded presentations) and a subsequent Q&A session.
- **Speakers should be virtually present for their entire session** in order to answer questions and participate in the discussion.
- A session chair is assigned to each session to introduce the presenters, facilitate and oversee time, and the Q&A period. A session coordinator is also assigned to each parallel session to manage the order of the presentations, initiate playback of the pre-recorded presentations and ensure smooth transitions between presentations.
- Pre-recorded presentations are managed by the session coordinator according to the established schedule (see Session Plan).
- A common Q&A session will follow the presentations in each session. The session chair will lead the Q&A period and time allotted.
- Please ensure that your **webcam is on during the Q&A session** so that attendees can view you.
- The participants may submit their questions verbally (You can use the **Raise your hand** tool to inform the session chair if you want to raise a question verbally) or via **Chat**. The session chair will choose the most relevant ones to read for presenters to answer during the Q&A period.
- The **Chat** tool can also be used by session chair and session coordinator to privately contact the presenters if needed. If you need technical assistance, you can inform the session coordinator using this tool.

- ## To Access WCS 2025 Hybrid Symposium

To access the symposium virtually:

Join the 13th World Construction Symposium https://us05web.zoom.us/j/86918470014?pwd=OySQC8AVtfr3GmQXVRqVFalccEXaEi.1
Meeting ID: 869 1847 0014 Passcode: wcs2025

- Make sure to install Zoom on your computer or update it to the latest version (version 5.3.0 or higher).
- Use the Meeting ID and passcode provided by the Symposium Secretariat to log on to the Main Meeting Room of the symposium. (The symposium inauguration, panel discussion and the sum-up are held in the WCS2023 main meeting room).
- Parallel paper presentation sessions are held in breakout rooms within the main meeting room. Once, the breakout rooms are open, you will be able to select and enter a breakout room of your choice. All registered attendees can attend all parallel sessions and switch from session to session at will. [Note: Participants not joined with the desktop or mobile app (version 5.3.0 or higher) may not be able to self-select a breakout room and will need to be assigned by the Host].
- To join the parallel session of your choice:
    - Click **Breakout Rooms** in your meeting controls.

      This will display the list of open breakout rooms (i.e. parallel sessions) created by the host.
    - Hover your pointer over the number to the right of breakout room you wish to join, click **Join**, then confirm by clicking Join.
    - Repeat as necessary to join other breakout rooms.
    - You can leave the breakout room and return to the main meeting room at any time, or you can leave the meeting entirely from the breakout room.
    - To leave the breakout room click **Leave Breakout Room** and choose if you want to leave the breakout room or the entire meeting (if you want to switch to a different parallel session, make sure to use the 'Leave Room' option to re-enter the main meeting room and join a different parallel session).
    - When the host ends the breakout rooms, you will be notified and given the option to return to the main room immediately, or in 60 seconds.

- ## Virtual Background for Zoom

- You can use an optional virtual background with your university/company logo to hide or standardise your backstage during your parallel session and/or symposium group photo (refer Symposium Agenda).
- We recommend that you do a test beforehand to see which background works better for you, depending on your environment.
- Please click here for instructions on enabling virtual backgrounds on Zoom.

- ## Some other Useful Links

If you need more information on how to use Zoom:

How to join a Zoom meeting

How to configure your audio and video Participating in breakout rooms

- ## Language

The official language of the symposium is English. There will be no simultaneous translations.

- ## Dress Code

For the symposium: business, lounge or national attire

For the fellowship and awards night: formal attire

- ## Awards

  - CIOB Best Paper Award
  - CIOB - Highly Commended Paper Award
  - BEPAM Best Paper award – with a certificate and a prize of free access to Emerald Insight for a period of 90 days and 40 free downloads for the author(s) of this Best paper
  - Two (02) BEPAM Highly Commended Paper awards – with a certificate for the author(s) of each Highly Commended Paper

- ## Certificate of Attendance

  - A certificate of attendance will be issued to all authors, after the respective parallel sessions. The authors who participated the symposium virtually will receive the e-certificates in due course.

Disclaimer

Whilst every attempt be made to ensure that all aspects of the symposium mentioned in this announcement will take place as scheduled, the Organising Committee reserves the prerogative to make last minute changes should the need arise without prior notice.

MESSAGE FROM THE SYMPOSIUM CHAIRPERSON

Prof. Chitra Weddikkara

Chairperson
The 13th World Construction Symposium 2025

It is my honour and privilege to welcome you to the 13th World Construction Symposium, a flagship event in Sri Lanka's academic and professional calendar. Over the past thirteen years, this symposium has evolved into a leading platform that unites scholars, practitioners, and industry leaders to exchange ideas, share innovations, and explore pathways to address the challenges and opportunities in the construction sector. Organized under the patronage of the Ceylon Institute of Builders (CIOB) and the Building Economics and Management Research Unit (BEMRU) of the Department of Building Economics, University of Moratuwa, it serves as a unique forum for reflection, engagement, and collaboration.

This year's theme, "*Sustainable Futures: Shaping a Regenerative Built Environment for Future Generations*," highlights the crucial role of the construction industry in steering global efforts towards sustainability. Our responsibility extends beyond meeting immediate infrastructural needs. It is about shaping a regenerative future that ensures resilience, inclusivity, and prosperity for generations to come.

I extend my sincere appreciation to our sponsors, partners, and the organising committee, whose commitment and dedication have been instrumental in making this event a success. Their efforts ensure that the symposium continues to foster meaningful conversations that inspire actionable outcomes.

As we embark on this year's sessions, let us seize the opportunity to exchange knowledge, challenge conventional thinking, and co-create solutions that will shape a more sustainable and regenerative built environment. Thank you for joining us at the 13th World Construction Symposium and I look forward to the stimulating discussions and fruitful collaborations to follow.

MESSAGE FROM THE PRESIDENT, CIOB

Dr. Rohan Karunaratne

President
The Ceylon Institute of Builders (CIOB)

I take great pleasure in welcoming you to the 13th World Construction Symposium (WCS) 2025 on the theme "*Sustainable Futures: Shaping a regenerative Built Environment for future generations*" to be held on the 15th and 16th August 2025 in Colombo. CIOB's WCS is an exciting annual venture organized jointly with the Building Economics and Management Research Unit (BEMRU) of the Department of Building Economics of the University of Moratuwa, Sri Lanka.

The purpose and vision of this symposium is the promotion of academic and research activities in the field of Sustainable Construction. The Symposium will bring all like-minded individuals on a single platform to discuss new trends and challenges in the field of Sustainable Construction. During its proceedings, Sri Lankan academics, research scholars and practitioners will get the opportunity to interact with renowned experts from overseas on sustainable construction and new trends in global built environment.

The CIOB is honoured to have a distinguished team of academics and researchers to serve on the scientific committee, providing comprehensive reviews to the submissions. The extensive technical programme developed by the scientific committee, includes five concurrent sessions/presentation tracks. The event gives an opportunity for the professionals in the construction industry to achieve targets on their Continued Professional Development.

I wish the symposium to be a great success with your continued participation and the commitment of the University of Moratuwa and the generous support of all from the Sri Lankan Construction Industry.

MESSAGE FROM THE HON. SECRETARY, CIOB

Eng. Saliya Kaluarachchi

Hon. Secretary
The Ceylon Institute of Builders (CIOB)

I am pleased to welcome all the delegates to the 13th World Construction Symposium, 2025 held during the period 15th and 16th August 2025 in Colombo. It is with great pleasure I apprise you that our institute, the Ceylon Institute of Builders has been able to host the World Construction Symposium annually since 2012. The Symposium has become a popular event for both the academics and professionals in the Construction industry in Sri Lanka. I am sure that this Symposium will live up to their expectations and enable the participants to gain knowledge from the presentations and the discussion during its two-day proceedings.

The Building Economics and Management Research Unit (BEMRU) of the Department of Building Economics of the University of Moratuwa, Sri Lanka is the joint organizer of this Symposium along with the CIOB. I would like to express gratitude to them for their firm commitment and backing in making this a continued reality. I am also thankful to the Associate Partners of the Symposium which include leading academic and research institutions from a number of countries.

As in the previous years, this year also the Symposium has been greatly supported by the Construction industry stakeholders and professional institutions in organizing the event. I wish to record my special thanks to all of our Sponsors and well-wishers for their generous contribution to make this symposium a success.

My best wishes to all those who have joined this year's conference for gaining and spreading knowledge on sustainable built environment for sustainable futures.

MESSAGE FROM THE SYMPOSIUM CO-CHAIRPERSONS

Eng. Sagara Gunawardena

Dr. Kalana Alwis

Mr. Ranji Hewage

Co-Chairpersons
Organizing Committee
The 13th World Construction Symposium

We are pleased to welcome all distinguished delegates to the 13th World Construction Symposium 2025 (WCS 2025) to be held during 15th and 16th August 2025 in Colombo. This annual symposium has been jointly organized by the Ceylon Institute of Builders (CIOB) and the Department of Building Economics of the University of Moratuwa since the year 2012. The theme for this year's symposium is "*Sustainable Futures: Shaping a Regenerative Built Environment for Future Generations*" which is timely in the context of the growing need to keep in line with the global trends and the sustainable goals in the construction industry.

During the past decade, the CIOB has taken a number of initiatives with the University of Moratuwa through this highly acknowledged event to play a leading role in the sustainable development process for the construction industry both in Sri Lanka and globally. This has further strengthened integrated multidisciplinary teams to develop a number of appropriate technologies in the field of research and development.

Recognition of such outstanding research achievements among the researchers is a great motivating factor. Achievements by academic and professional bodies together are also a great encouragement for the industry and for further research.

We congratulate and appreciate the collective work done by all those stakeholders for the Construction Industry over the years and recognize the achievement of the Scopus indexed accomplishment as a significant achievement for the WCS by the University of Moratuwa.

We wish the WCS 2025 every success in its proceedings.

MESSAGE FROM HEAD, DEPARTMENT OF BUILDING ECONOMICS, UNIVERSITY OF MORATUWA

Prof. Anuradha Waidyasekara

Head of the Department
Department of Building Economics
University of Moratuwa

I extend my warmest wishes for the 13th World Construction Symposium 2025. This international event is jointly organized by the Building Economics and Management Research Unit (BEMRU) of the Department of Building Economics, University of Moratuwa, Sri Lanka and the Ceylon Institute of Builders (CIOB). The symposium brings together several esteemed national and international partners, including Western Sydney University, Australia; The University of Newcastle, Australia; Deakin University, Australia; Massey University, New Zealand; the University of Adelaide, Australia; Indian Institute of Technology Madras (IIT Madras), India; Dr. Bhanuben Nanavati College of Architecture, India; Built Environment Project and Asset Management (BEPAM) Journal, published by Emerald Group Publishing; Colombo School of Construction Technology (CSCT), Sri Lanka.

The global construction industries are transforming with sustainable futures, navigating through economic pressures, resource constraints, climate change, and trade wars. The 13th World Construction Symposium is themed "*Sustainable Futures: Shaping a Regenerative Built Environment for Future Generations*", reflecting its forward-looking and action-oriented approach.

This year's symposium provides an excellent platform for local and international delegates to share knowledge, exchange experiences, and present sustainable solutions and research findings that address contemporary challenges in the construction industry. I encourage all participants to make the most of this opportunity to engage in meaningful discussions, build networks, and contribute to the collective advancement of our industry.

I wish the 13th World Construction Symposium 2025 every success and look forward to its continued contribution towards shaping a sustainable and innovative construction future.

SYMPOSIUM PROGRAMME

FRIDAY, 15 AUGUST 2025 – DAY ONE	
08.30 am	Symposium Registration
09.00 am	Symposium Inauguration
09.10 am - 09.20 am	Welcome address by President, CIOB **Dr. Rohan Karunaratne**
09.20 am - 09.30 am	Address by Conference Chairperson **Prof. Chitra Weddikkara**
09.30 am - 09.40 am	Address by Deputy Vice Chancellor **Prof. D. P. Chandrasekara**
09.40 am -10.00 am	Address by the Chief Guest **Prof. Malik Ranasinghe**
10.00 am - 10.30am	Keynote Address 1 ***"Building Resilient Communities: Lessons from the UK Flood and Coastal Resilience Innovation Programme (FCRIP)"*** **Prof. David Proverbs**
10.30 am- 10.35 am	Sponsors Video
10.35 am- 10.55 am	Refreshments
10.55 am – 11.10 am	Address by Editor-in-Chief, Journal of Built Environment Project and Asset Management (BEPAM) **Prof. Mohan Kumaraswamy**
11.10 am – 11.40 am	Keynote Address 2 ***"Sustainability and Circularity through Digitalisation"*** **Prof. Srinath Perera**
11.40 am – 11. 50 am	Sponsors Video
11.50 am – 12.00 noon	Vote of Thanks by Hony. Secretary, CIOB **Eng. Saliya Kaluarachchi**
12.00 noon - 01.00 pm	Lunch Break
0 1.00 pm - 03.00 pm	**Parallel Sessions 1**
03.00 pm - 03.30 pm	Refreshments
03.30 pm - 05.30 pm	**Parallel Sessions 2**
05.30 pm	End of Day 1

SATURDAY, 16 AUGUST 2025 – DAY TWO	
08.00 am	Symposium Registration
08.30 am - 10.00 am	**Parallel Sessions 3**
10.00 am - 10.30 am	Refreshments
10.30 am - 12.00 noon	**Parallel Sessions 4**
12.00 noon - 01.30 pm	Lunch Break
01.30 pm - 03.15 pm	**Panel Discussion on:** **"2030 Step Ahead: Strategic Foresight for the Sri Lankan Construction Industry"** **Panel Members:** Prof. David Proverbs Prof. Srinath Perera Prof. Chitra Weddikkara Dr. Rohan Karunaratne Dr. Kalana Alwis **Panel Moderator:** Ch.QS. Lalith Ratnayake **Thematic Summary Contributor:** Dr. Suranga Jayasena
03.15 pm - 03.25 pm	Announcing the Award Winners **Prof. Mohan Kumaraswamy** **Prof. Anuradha Waidyasekara**
03.25 pm - 03.35 pm	Vote of Thanks by Scientific Committee Co-Chairperson **Dr. Indrani Wimalaratne**
03.35 pm - 04.00 pm	Refreshments
04.00 pm	End of Programme
06.30 pm Onwards	Awards Ceremony & Symposium Dinner at Hilton Colombo

DETAILED SESSION PLAN

FRIDAY, 15 AUGUST 2025

SESSION 1A

Theme	**Carbon Assessment in the Built Environment**
Session Chair	**A/Prof. Sepani Senaratne**
Venue/Time	**Room A - 01.00 PM - 03.00 PM**
Virtual	**Breakout Room - Session A**

Time	Paper ID, Title and Author(s)
01.00 PM - 01.15 PM	**S17045: Global Research Trends in Carbon Capture and Utilization Technologies for Cement Production: A Bibliometric Analysis** *H.H.A.P Hemantha, R.A.B.U.N. Perera, D.N.L.S. Uduwage*
01.15 PM - 01.30 PM	**S17052: Embodied Carbon Variability in Indian High-Rise Residential Buildings: A Case-Based Assessment** *K.G. Akshatha, Sivakumar Palaniappan, M.K. Pradeep Kumar Rao*
01.30 PM - 01.45 PM	**S17062: Carbon Financing in Construction: Review of Benefits and Barriers** *D.S.I. Wijayawardena, K.A.T.O. Ranadewa*
01.45 PM - 02.00 PM	**S17074: Learning from Nature: Biomimicry-Inspired Building Design for Carbon Reduction in Urban Living** *R.V.A.D. Rahubadda, Udayangani Kulatunga, A.P. Rathnasinghe*
02.00 PM - 02.15 PM	**S17075: Project Data Responsibilities for Carbon Assessment in Sri Lankan Construction Industry** *R.M.T.D. Rajapaksha, S.D. Gallage*
02.15 PM - 02.30 PM	**T17125: The Applicability of Carbon Emission Estimation with BIM Environment: Sri Lankan Context** *D.A.M.V. Perera, C. Allis, B.K.C. Perera, A. Lokuge*
02.30 PM - 03.00 PM	**Q&A**

Session Coordinator: Ch. QS Dilshan Akalanka

FRIDAY, 15 AUGUST 2025

SESSION 1B (Hybrid)

Theme	**Circular Economy Integration in Construction**
Session Chair	**Dr. Gayani Karunasena**
Venue/Time	**Room B - 01.00 PM - 03.00 PM**
Virtual	**Breakout Room - Session B**

Time	Paper ID, Title and Author(s)
01.00 PM - 01.15 PM	**S17011: Buildings Designed for Systemic Circularity: A Comprehensive Review of Methodological Taxonomies** *Prince Antwi-Afari, Daniel Oteng, S. Thomas Ng, Frank Ato Ghansah, Zhikang Bao*
01.15 PM - 01.30 PM	**S17129: Exploring Circular Building Material: Transforming Industrial and Agricultural Waste into 3D Printable Construction Material** *T. Takale, V. Anagal*
01.30 PM - 01.45 PM	**S17130: Mapping Circularity Parameters: A Literature Review of Policy Planning in the Built** *Environment* *R. Deshmukh, A. Garud, V. Anagal, S. Karve, M.* Siriwardena, A. Manewa
01.45 PM - 02.00 PM	**S17131: Investigating Business Models for Circular Economy Integration in Construction Sector** *S. Shah, A. Garud, V. Anagal, S. Karve, M. Siriwardena, A. Manewa*
02.00 PM - 02.15 PM	**S17134: From Policy Presence to Enforceability: Evaluating Water Circularity in the Indian Construction Frameworks** *N. Sakhardande, S. Karve, V. Anagal, A. Garud, A. Manewa, M. Siriwardena*
02.15 PM - 02.45 PM	**Q&A**

Session Coordinator: Mr. Lakshitha Bandaranayake

FRIDAY, 15 AUGUST 2025

SESSION 1C

Theme	**Enabling Digital Transformation in Sri Lankan Construction**
Session Chair	**Ch. QS Indunil Senevirathne**
Venue/Time	**Room C - 01.00 PM - 03.00 PM**
Virtual	**Breakout Room - Session C**

Time	Paper ID, Title and Author(s)
01.00 PM - 01.15 PM	**S17048: Addressing Data Management Challenges in Sri Lankan Construction Industry through Blockchain Integration** *W.M.N.D. Wijesundara, M. Thayaparan, M.D.D. Costa*
01.15 PM - 01.30 PM	**S17068: Exploring The Potential of Blockchain Technology Adoption in the Sri Lankan Construction Industry: Opportunities and Barriers to Implementation** *D.W.J.W. Bandara, P.L.I. Wimalaratne, Udayangani Kulathunga, A. Wijayasiri*
01.30 PM - 01.45 PM	**S17092: Integrating BIM into Business Models of Consultancy Firms: Barriers and Enablers** *R.L. Samaraweera, D.N. Abeynayake, S. Sivanraj*
01.45 PM - 02.00 PM	**S17105: Barriers to Adopting Digital Twin Technology for Contract Administration in Sri Lankan Construction Sector** *M.K.L.I.C. Fernando, V. Lingasabeshan, P.L.I. Wimalaratne*
02.00 PM - 02.15 PM	**S17109: Applicability of Artificial Intelligence Models for Selection of ADR Methods to the Settlement of Contractor-Related Variation Disputes in Building Construction Projects in Sri Lanka** *Y.M.W.H.M.R.R.L.J.B. Kiridana, M.D.T.E. Abenayake*
02.15 PM - 02.30 PM	**S17115: Barriers and Solutions to Adopting Digital Twin in Sri Lankan Construction** *H.T.T.A. Indunil, R.P.H.S. Bandara, P.H.Y. Buddhini*
02.30 PM - 03.00 PM	**Q&A**

Session Coordinator: Ms. Dasuni Kodithuwakku

FRIDAY, 15 AUGUST 2025

SESSION 1D

Theme	**Technology-Driven Innovations for Safety and Productivity in Construction**
Session Chair	**Prof. Nayanthara De Silva**
Venue/Time	**Room D - 01.00 PM - 03.00 PM**
Virtual	**Breakout Room - Session D**

Time	Paper ID, Title and Author(s)
01.00 PM - 01.15 PM	**S17033: Detection of Mobile Phone Use by Labourers on Construction Sites using YOLOv11-s** *D.N.L.S. Uduwage, S. Sivanraj, K.G.A.S. Waidyasekara, R.K. Shiwakoti, M.Tripathi*
01.15 PM - 01.30 PM	**S17034: Comparison of Yolo Algorithms for PPE Compliance Monitoring at Construction Sites** *S. Sivanraj, D.N.L.S. Uduwage, M. Tripathi*
01.30 PM - 01.45 PM	**S17054: Examining Health and Safety Management among Foreign Contractors in Sri Lanka: Gaps, Barriers, and Improvement Strategies** *B.G. Wijayarathna, C. Allis, Y.K. Delpachitra*
01.45 PM - 02.00 PM	**S17110: Enhancing Labour Productivity in the Sri Lankan Construction Industry through Computer Vision** *E.M.K.K. Ekanayaka, B.A.I. Eranga*
02.00 PM - 02.15 PM	**T17122: IOT-Based Real-Time Monitoring Systems to Enhance Workers' Safety in High-Rise Construction Projects in Sri Lanka** *S.S. Jayasundara, B.A.I. Eranga*
02.15 PM - 02.45 PM	**Q&A**

Session Coordinator: Ms. Piumi Tennakoon

FRIDAY, 15 AUGUST 2025

SESSION 1E

Theme	**Lean Integration for Sustainable Construction**
Session Chair	**Dr. Mohan Siriwardena**
Venue/Time	**Room E - 01.00 PM - 03.00 PM**
Virtual	**Breakout Room - Session E**

Time	Paper ID, Title and Author(s)
01.00 PM - 01.15 PM	**S17032: BIM Implementation by Integrating Lean Construction and IDT (LCIDT)** *Rhijul Sood, Nandini Sharma, Boeing Laishram*
01.15 PM - 01.30 PM	**S17056: Client Satisfaction Model for Lean Implemented Construction SMEs: A Review** *K.G.P.N. Munasingha, K.A.T.O. Ranadewa, M.R.D.P. Wijerathna*
01.30 PM - 01.45 PM	**S17063: Lean Thinking for Green Building: Barriers for Lean Integrated Sustainable Construction** *S.J.L. Madhushani, K.A.T.O. Ranadewa, L.D.I.P. Seneviratne*
01.45 PM - 02.00 PM	**S17100: Lean Integrated Business Model for Construction - A Systematic Review on Current Practices and Future Directions** *P.W.A.H. Lawanga, Y.G. Sandanayake, K.A.T.O. Ranadewa*
02.00 PM - 02.15 PM	**S17104: Lean Integrated Circular Economy in the Sri Lankan Construction Industry: A Qualitative Delphi Study** *Hariis Vijayakumar, K.A.T.O. Ranadewa, Panchali Weerakoon, Agana Parameswaran, J.K.D.D.T. Jayanetti*
02.15 PM - 02.30 PM	**S17107: Integration of Lean Kaizen Model to Enhance Material Efficiency in Construction Projects: A Literature Review** *Sathursiya Selasteen, B.A.K.S. Perera, Anuki S. Kavirathna*
02.30 PM - 03.00 PM	**Q&A**

Session Coordinator: Ms. Dewmini Wijerathne

FRIDAY, 15 AUGUST 2025

SESSION 2A

Theme	**Advancing Circular Economy Practices and Policy in the Built Environment**
Session Chair	**Dr. Dilani Abeynayake**
Venue/Time	**Room A - 03.30 PM - 05.30 PM**
Virtual	**Breakout Room - Session A**

Time	Paper ID, Title and Author(s)
03.30 PM - 03.45 PM	**S17025: Private Sector Role as a Key Stakeholder Towards the Circular Economy in the Construction Industry in Sri Lanka** *N.V.J. Chathurya, K.A.N. Gunarathna, Kavini Guruge*
03.45 PM - 04.00 PM	**S17072: Moving from Linear to Circular Apparel Economy in Sri Lanka: PRISMA-Based Analysis of Circular Economy and Supply Chain Interactions** *C.H. Kumara, Harshini Mallawaarachchi, J.A.D.K.S. Jayakodi*
04.00 PM - 04.15 PM	**S17088: Competencies of Construction Professionals to Perform Circular Economy Practices: A Systematic Review** *D.S.I. Wijayawardena, Iresha Gamage, Sepani Senaratne, B.A.K.S. Perera*
04.15 PM - 04.30 PM	**S17097: A Review on Circular Economy and its Synergy with Industrial Symbiosis** *Angel Lokuge, Gihan Anuradha Tennakoon, Udayangani Kulatunga*
04.30 PM - 04.45 PM	**S17108: Comparison of Legislation of UK and Sri Lanka for Better Implementation of Circular Economy in Sri Lankan Construction Industry** *M.D.T.E. Abeynayake, B.A.K.S. Perera*
04.45 PM – 05.00 PM	**S17132: Review of Circularity Assessment Tools in the Built Environment** *S. Shende, V. Anagal, A. Manewa, S. Karve, A. Garud, M. Siriwardena*
05.00 PM - 05.30 PM	**Q&A**

Session Coordinator: Ms. Nimaya Perera

FRIDAY, 15 AUGUST 2025

SESSION 2B (Hybrid)

Theme	**Digital Transformation and Technology Adoption in Construction**
Session Chair	**Dr. Navodana Rodrigo**
Venue/Time	**Room B - 03.30 PM - 05.15 PM**
Virtual	**Breakout Room - Session B**

Time	Paper ID, Title and Author(s)
03.30 PM - 03.45 PM	**S17006: Assessing Organisational Readiness for Digital Transformation: Key Attributes for Indigenous South African Construction Firms** *Mayowa Adedapo Ogungbe, Matthew Ikuabe, Clinton Ohis Aigbavboa*
03.45 PM - 04.00 PM	**S17007: Defining Green Building Criteria for Building Information Modeling-Based Rating Systems** *Mustika Sari, Mohammed Ali Berawi, Rahmadi Surya, Gunawan Saroji, Nunik Madyaningarum, Siti Rahma Utami, Rafly Muzady*
04.00 PM - 04.15 PM	**S17085: Towards a Computerised Maintenance Management System for Healthcare Facilities in South Africa** *Matthew Ikuabe, Clinton Aigbavboa, Bankole Awuzie, Mayowa Ogungbe*
04.15 PM - 04.30 PM	**S17090: Barriers to Adoption of Automation in Indian Construction Projects** *Mohammed Akberuddin Adnan, Santhosh Loganathan*
04.30 PM - 04.45 PM	**S17103: A Review of Procurement and Management of Building Services Systems: Complexities and Technology Adoption** *Sachindra Hewavitharana, Srinath Perera, Xiaohua Jin, Krisanthi Seneviratne, Keivan Bamdad*
04.45 PM – 05.15 PM	**Q&A**

Session Coordinator: Mr. Lakshitha Bandaranayake

FRIDAY, 15 AUGUST 2025

SESSION 2C

Theme	**Sustainable Construction and Circular Economy Strategies**
Session Chair	**Prof. Lalith De Silva**
Venue/Time	**Room C - 03.30 PM - 05.30 PM**
Virtual	**Breakout Room - Session C**

Time	Paper ID, Title and Author(s)
03.30 PM - 03.45 PM	**S17058: Towards Successful Implementation of Offsite Construction in Sri Lanka: Barriers and Strategies** *L.P.T. Manodya, R.P.H.S. Bandara, P.H.Y. Buddhini*
03.45 PM - 04.00 PM	**S17023: Unlocking Efficiency in Timber Frame Construction: A Comparative Study of On-Site vs. Off-Site Approaches in Scotland** *Georgia Fraser, Nirodha Fernando, Deeksha Sharma*
04.00 PM - 04.15 PM	**S17031: Potential Use of Plastic Waste as a Sustainable Construction Material in Sri Lanka** *S. Geerthanan, S. Sivanraj*
04.15 PM - 04.30 PM	**S17043: Optimising Material Selection for Design for Deconstruction: A Kano Model-Based Evaluation of Doors and Windows** *P.H.G.M.A. Ranasinghe, K.G.A.S. Waidyasekara, D.N.L.S. Nuwantha*
04.30 PM - 04.45 PM	**S17050: Green Adaptive Re-Use of Buildings in Sri Lanka** *H.G.S. Dushmantha, Udayangani Kulatunga, N.B. Nanayakkara, W.S.D Perera*
04.45 PM – 05.00 PM	**S17059: Towards a Circular Economy: Evaluating Effective Implementation Strategies for Recycling and Reuse Programmes in Sri Lanka's Construction Industry** *S.D.V. Lakshan, W.M.C.L.K. Wijekoon, P.H.Y. Buddhini*
05.00 PM - 05.30 PM	**Q&A**

Session Coordinator: Ms. Anuki Kavirathna

FRIDAY, 15 AUGUST 2025

SESSION 2D

Theme	**Human-Centered and Technological Approaches to Urban Disaster Resilience**
Session Chair	**Dr. Sachie Gunathilake**
Venue/Time	**Room D - 03.30 PM - 05.30 PM**
Virtual	**Breakout Room - Session D**

Time	Paper ID, Title and Author(s)
03.30 PM - 03.45 PM	**S17013: Disaster-Resilient Cities: Temporal Analysis of Urban Land Use Land Cover Changes and Urban Floods from 1999 To 2022: Case Study of Colombo, Sri Lanka** *U. Abeysinghe, H.U.C.P. Hewawasam, J. Manatunga*
03.45 PM - 04.00 PM	**S17039: Sustainable Urban Mobility in Sri Lanka: The Imperative for an Inherent Human-Centered Approach for Holistic Development** *J.A.C.D. Jayalath, Udayangani Kulatunga*
04.00 PM - 04.15 PM	**S17061: Review on Technological Interventions to Enhance Flood Resilience in the Built Environment** *R.P.T. Nayanathara, M. Thayaparan*
04.15 PM - 04.30 PM	**S17098: Serious Games for Disaster Risk Reduction: Enhancing Community Preparedness for Sustainable Futures** *Udayangani Kulatunga, H. Tariq*
04.30 PM - 04.45 PM	**S17111: Crowdfunding for Post-Disaster Reconstruction Projects: A Conceptual Framework** *M.R.M. Riskan, K.D. Sepalage, D. Weerasooriya, K.A.T.O. Ranadewa*
04.45 PM – 05.00 PM	**S17126: A Human Centred Approach to Post Disaster Resettlement Housing: Case Study on Walk-Up Apartments in Sri Lanka** *M.S.N. de Zoysa, S.B.A. Coorey, M. Thayaparan, L. de Silva*
05.00 PM - 05.30 PM	**Q&A**

Session Coordinator: Mr. Yasith Sandaruwan

FRIDAY, 15 AUGUST 2025

SESSION 2E

Theme	**Digital Innovations and Strategies for Energy Management in Built Environments**
Session Chairs	**Dr. Chandanie Hediwattage**
Venue/Time	**Room E - 03.30 PM - 05.30 PM**
Virtual	**Breakout Room - Session E**

Time	Paper ID, Title and Author(s)
03.30 PM - 03.45 PM	**S17037: Developing a Satellite-Enabled Digital Twin Ecosystem Framework for Energy Monitoring in Smart Cities in Sri Lanka: A Literature Review** *Rusin Thathsara, Harshini Mallawaarachchi*
03.45 PM - 04.00 PM	**S17042: Short-Term Electricity Demand Forecasting in Sri Lanka Using Statistical and Deep Learning Models** *Ranju Kumari Shiwakoti, Piya Limcharoen, D.N.L.S. Uduwage*
04.00 PM - 04.15 PM	**S17049: IOT Implementation for Energy Management within Residential Buildings in Sri Lanka: Drivers and Barriers** *P. Theiventhiralingam, S. Sivanraj, K.H.K Dharmadasa, Udayangani Kulathunga*
04.15 PM - 04.30 PM	**S17071: The Effect of Vertical Greenery Systems on Building Energy Performance: Overall Thermal Transfer Value-Based Comparative Analysis** *R.A.A. Munsif, Harshini Mallawarachchi, Dimuthu Vijerathne*
04.30 PM - 04.45 PM	**S17073: Building Energy Data Management Systems in the World: A Review** *S.D.R.Y. Silva, H.W.N. Madhusanka, K.A.R.V.D. Kahandawa*
04.45 PM – 05.00 PM	**S17079: An Investigation into Effective Energy Behavior Control Strategies in the Apparel Manufacturing Sector** *N. Premananth, S.D.A. Soorige*
05.00 PM - 05.30 PM	**Q&A**

Session Coordinator: Ms. Nawanjana Manapperuma

SATURDAY, 16 AUGUST 2025

SESSION 3A

Theme	**Innovations in Sustainable Facilities and Maintenance Management**
Session Chair	**Dr. Tharusha Ranadewa**
Venue/Time	**Room A - 08.30 AM - 10.00 AM**
Virtual	**Breakout Room - Session A**

Time	Paper ID, Title and Author(s)
08.30 AM - 08.45 AM	**S17080: Rainwater Harvesting Systems as a Sustainable Water Management Strategy: Addressing Water Security Challenges in Sri Lankan Buildings** *W.M.S.D. Wijerathna, G.A.K. Dulshan, K.A.S.H. Wjayasenarathne, R.M.A. Dilini*
08.45 AM - 09.00 AM	**S17081: Applicability of Lean Maintenance Practices to Mitigate Maintenance Management Issues in Sri Lankan High-Rise Residential Buildings** *U.H.M.S. Samaranayaka, U. Rathnayake, A.S.W Karunarathna*
09.00 AM - 09.15 AM	**S17089: Shaping Regenerative Stormwater Management: A Conceptual Framework for Blue-Green Infrastructure** *H. Nethmini, C. Hadiwattage, S. Sivanraj, M.M.N. Mannapperuma*
09.15 AM - 09.30 AM	**S17101: Assessing the Impact of Organisational Culture on Digital Transformation in the Sri Lankan Facilities Management Industry** *A.S.W. Karunarathna, Jayantha Wadu Mesthrige*
09.30 AM - 09.45 AM	**S17102: Identifying Maintenance Training Needs in Sri Lanka's Apparel Industry and Augmented Reality as a Strategic Solution** *W.M.I.H. Wijesundara, P. Sridarran, P.A.P.Y. Gajaba*
09.45 AM – 10.00 AM	**Q&A**

Session Coordinator: Mr. Kawshalya Sepalage

SATURDAY, 16 AUGUST 2025

SESSION 3B (Hybrid)

Theme	**Sustainability, Social Impact, and Workforce in Global Construction**
Session Chair	**A/Prof. Gajendran Thayaparan**
Venue/Time	**Room B - 08.30 AM - 10.00 AM**
Virtual	**Breakout Room - Session B**

Time	Paper ID, Title and Author(s)
08.30 AM - 08.45 AM	**S17004: Coping Strategies Adopted by Inhabitants with Asbestos Cement Roof Houses in South African Legacy Township** *Nonhlanhla Maphoso, Christopher Amoah*
08.45 AM - 09.00 AM	**S17087: Assessing Key Risk Factors for Workers During Nighttime in the Indian Construction Industry** *Naman Srivastava, Rohit Sahu, Sparsh Johari*
09.00 AM - 09.15 AM	**S17113: Community Benefit and Engagement Frameworks in Australian Renewable Energy Transition: A Thematic Analysis** *Umesha Weerapperuma, Navodana Rodrigo, M.K.C.S. Wijewickrama, George Zillante*
09.15 AM - 09.30 AM	**T17118: Assessing Factors Influencing Worker Retention in the Indian Construction Industry** *Akumoni Pegu, Rohit Sahu, Sparsh Johari*
09.30 AM - 09.45 AM	**S17135: Sustainable Solar: Addressing the Growing Need for PV Panel Recycling** *Tariq Umar, Sa'id Ahmed, Muhammad Qasim Rana*
09.45 AM – 10.00 AM	**Q&A**

Session Coordinator: Ms. Piumi Tennakoon

SATURDAY, 16 AUGUST 2025

SESSION 3C

Theme	**Innovative Data-Driven Approaches for Cost and Quality Optimization in Construction**
Session Chair	**Senior Prof. Kanchana Perera**
Venue/Time	**Room C - 08.30 AM - 10.00 AM**
Virtual	**Breakout Room - Session C**

Time	Paper ID, Title and Author(s)
08.30 AM - 08.45 AM	**S17001: Perceived and Expected Cost Optimization Affordances of Building Information Modelling in Sri Lankan Construction Projects** *J. Logendran, S. Sivanraj, V. Lingasabesan, Himal Suranga Jayasena, B.A.I. Eranga*
08.45 AM - 09.00 AM	**S17005: A Study Assessing the Application of Artificial Neural Network for Preliminary Estimation in Sri Lankan Building Projects** *U.P. Wijerathne, Udayangani Kulatunga, M.L.S.S. Fernando*
09.00 AM - 09.15 AM	**T17008: Predicting Cost Elements of Construction Projects Using Supervised Machine Learning Techniques** *K.A.M. Rasila, I. Mahakalanda, M.W. Edirisooriya*
09.15 AM - 09.30 AM	**S17036: Optimizing Quality Management in the Construction Industry: A COQ-Based Predictive Analysis** *Nandini Sharma, Rhijul Sood, Boeing Laishram*
09.30 AM - 09.45 AM	**S17128: Exploring Perceptual Mapping Technique as an Innovative Method of Representing Construction Cost Information** *D.N.L.S. Uduwage, Himal Suranga Jayasena, S. Piranavan*
09.45 AM – 10.00 AM	**Q&A**

Session Coordinator: Mr. Yasith Sandaruwan

SATURDAY, 16 AUGUST 2025

SESSION 3D

Theme	**Policy, Education, and Sustainability Challenges**
Session Chairs	**Prof. Menaha Thayaparan**
Venue/Time	**Room D - 08.30 AM - 10.00 AM**
Virtual	**Breakout Room - Session D**

Time	Paper ID, Title and Author(s)
08.30 AM - 08.45 AM	**S17028: Constructing National Policy for Future Generations: A Design Approach to Children's Books** *S. Samarawickrama*
08.45 AM - 09.00 AM	**S17044: Decent Work Enforcement Gaps: Adapting Global Lessons into Sri Lankan Construction Industry** *Sathyami Dissanayake, D.N.L.S. Uduwage, R.A.B.U.N. Perera*
09.00 AM - 09.15 AM	**S17095: Evaluating the Effectiveness of Approved Document in Mitigating Overheating in Buildings: A Focus on Modern Methods of Construction** *Patience Isaac, Roshani Palliyaguru, R.A.B.U.N. Perera*
09.15 AM - 09.30 AM	**S17117: Impact of the Sri Lankan Government Economic Reform Programmes on the Construction Industry since Year 2022** *B. Gheethanjali, Y.G. Sandanayake, D.M.L.N. Bandaranayake*
09.30 AM - 09.45 AM	**S17136: Present Realities and Future Directions of AI Integration within Built Environment Higher Education** *L. Jones, A. Manewa, M. Siriwardena, V. Anagal, S, Karve, A. Guard*
09.45 AM – 10.00 AM	**Q&A**

Session Coordinator: Ms. Anuki Kavirathna

SATURDAY, 16 AUGUST 2025

SESSION 3E

Theme	**Sustainable Waste Management and Material Innovation in Construction**
Session Chair	**Prof. Udayangani Kulatunga**
Venue/Time	**Room E - 08.30 AM - 10.00 AM**
Virtual	**Breakout Room - Session E**

Time	Paper ID, Title and Author(s)
08.30 AM - 08.45 AM	**S17027: A Bibliometric Analysis of Computer Vision Applications in Construction and Demolition Waste Management** *A.S.W. Karunarathna, G.G.N. Chandani*
08.45 AM - 09.00 AM	**S17021: Utilization of Textile Industry By-Products to Develop and Optimize Geopolymerized Mud Concrete for Sustainable Construction** *K.G.C. Gayashani, R.K.N.P. Piyasena, D.A. Oshadhi, S.M. Young, R.U. Halwatura*
09.00 AM - 09.15 AM	**S17076: Impact of Material Waste Management on Construction Cost of the Projects in Sri Lankan Construction Industry** *Malith Jaypadma, Kumari Wijekoon, Hansi Deheragoda*
09.15 AM - 09.30 AM	**S17124: Bridging the Gap: Enabling a Secondary Material Market for Construction and Demolition Waste** *A.V.R.S. Kavindi, I.E. Illeperuma, M.D.T.E. Abeynayake*
09.30 AM - 09.45 AM	**S17047: Urban Symbiosis in Municipal Solid Waste Management and Reduction: Insights from a Bibliometric Review** *G.G.N. Chandani, A.S.W. Karunarathna*
09.45 AM – 10.00 AM	**Q&A**

Session Coordinator: Ms. Saambavi Sivanraj

SATURDAY, 16 AUGUST 2025

SESSION 4A

Theme	**Enhancing Construction Performance through Innovation and Management**
Session Chair	**Dr. Nuwantha Uduwage**
Venue/Time	**Room A - 10.30 AM – 12.00 NOON**
Virtual	**Breakout Room - Session A**

Time	Paper ID, Title and Author(s)
10.30 AM - 10.45 AM	**S17012: Readiness to Implement Construction 4.0 Applications in Building Construction Projects in Sri Lanka** *I.H.G.Y.M.W.U. Yaparathne, D.D. Dias, Kavini Guruge*
10.45 AM - 11.00 AM	**S17077: Barriers for Time, Cost, and Quality Management in Polymer Modified Asphalt Road Construction in Sri Lanka** *M.M. Nilanka, R.M.T.D. Rajapaksha, S.D. Gallage, D.M.L.N. Bandaranayake*
11.00 AM - 11.15 AM	**S17086: A Scoping Review of Construction SMEs: Global vs Local** *M.R.I.U.K. Ratnayake, M.R.D.P. Wijerathna, K.A.T.O. Ranadewa, B.A.K.S. Perera*
11.15 AM - 11.30 AM	**S17099: Buildability Momentum across Project Stages: Empirical Insights from RIBA Plan of Work towards Sustainable Construction** *P.L.I. Wimalaratne, Udayangani Kulatunga*
11.30 AM - 11.45 AM	**S17120: Early Commissioning of MEP Works for Better Building Performance** *Chathuranga Jayasinghe, Sachie Gunatilake, Dasuni Kodituwakku*
11.45 AM - 12.00 NOON	**S17019: Artificial Intelligence-Driven Systems for Enhancing Worker Safety Monitoring in Construction Environments: A Comprehensive Review** *J.A.U.S. Jayakody, P.R.H.N.G. Thilakarathna*
12.00 NOON - 12.15 PM	**Q&A**

Session Coordinator: Ms. Nimaya Perera

SATURDAY, 16 AUGUST 2025

SESSION 4B (Hybrid)

Theme	**Innovative Approaches for Improving Construction Project Performance**
Session Chair	**A/Prof. Sivakumar Palaniappan**
Venue/Time	**Room B - 10.30 AM – 12.00 NOON**
Virtual	**Breakout Room - Session B**

Time	Paper ID, Title and Author(s)
10.30 AM - 10.45 AM	**S17010: Impact of Constructability Issues in Large-Scale Condominium Projects: A Case Study for Sri Lanka** *N.H.V.T.N. Nanayakkra, K.P.H. Perera, R.U. Halwatura*
10.45 AM - 11.00 AM	**S17064: Identifying and Quantifying the Challenges of Sri Lankan Public-Private Partnerships: A Sentiment Analysis Approach** *Hirusheekesan Selvanesan, Udayangani Kulatunga, M.P.A.P. Wijayasiri*
11.00 AM - 11.15 AM	**S17067: Unpacking Agile Project Management in Indian Construction: Adoption Barriers, Industry Readiness and Sustainability Viewpoint** *Ankit Rakshit, Santhosh Loganathan*
11.15 AM - 11.30 AM	**S17116: Financial and Socio-Economic Impacts of Implementing Active Design Principles in South African Office Buildings** *Liezl Le Roux, Tascha Bremer*
11.30 AM - 11.45 AM	**S17123: Beyond Efficiency: Rethinking Off-Site Construction for Post-Disaster Housing Reconstruction** *A.P. Rathnasinghe, R.V.A.D. Rahubadda, N. Thurairajah, Udayangani Kulatunga*
11.45 AM - 12.00 NOON	**Q&A**

Session Coordinator: Ch. QS Dilshan Akalanka

SATURDAY, 16 AUGUST 2025

SESSION 4C

Theme	**Building Performance and Resilience through Defect Analysis and Evaluation**
Session Chair	**Dr. Anupa Manewa**
Venue/Time	**Room C - 10.30 AM – 12.00 NOON**
Virtual	**Breakout Room - Session C**

Time	Paper ID, Title and Author(s)
10.30 AM - 10.45 AM	**S17009: Causes, Detection and Remediation of Water-Induced Building Defects: A Systematic Review** *Argaw Gurmu, Dulani Denipitiya, Pabasara Upalakshi Wijeratne*
10.45 AM - 11.00 AM	**S17051: The Impact of Incremental Vertical Housing Development on Quality of Space and Residential Environmental Satisfaction: A Case Study of Swarna Place, Colombo, Sri Lanka** *M.S.M. Senarathna, A.A. Hettiarachchi*
11.00 AM - 11.15 AM	**S17055: Post Occupancy Evaluation (POE) in Government Office Buildings: A Literature Review** *H.D. Subhasingha, P.A.P.V.D.S. Disaratna, M.R.D.P. Wijerathna*
11.15 AM - 11.30 AM	**S17057: Improving Insulation in Sri Lankan High-Rise Buildings: Defects, Causes, and Selection Criteria** *M.P.G.I. Priyanjith, H.W.N. Madhusanka, K.A.D.M. Natasha*
11.30 AM - 11.45 AM	**S17096: A Conceptual Framework for Capacity Building in Physical Asset Resilience** *S.P. Koralage, P.A.D. Rajini, W.K.U.R.M.K.P.K. Samarakoon*
11.45 AM - 12.00 NOON	**Q&A**

Session Coordinator: Mr. Kawshalya Sepalage

SATURDAY, 16 AUGUST 2025

SESSION 4D

Theme	**Sustainability Performance and Practices in the Built Environment**
Session Chairs	**A/Prof. Nirodha Fernado**
Venue/Time	**Room D - 10.30 AM – 12.00 NOON**
Virtual	**Breakout Room - Session D**

Time	Paper ID, Title and Author(s)
10.30 AM - 10.45 AM	**S17041: Assessing SDG 7 Performance: Identifying Relevant KPIs for the Sri Lankan Construction Industry** *K. Thiruchelvam, D.N.L.S. Uduwage*
10.45 AM - 11.00 AM	**S17070: Strategic Approach for Overcoming Barriers to Sustainable Entrepreneurship in Sri Lankan Construction Industry** *R.P.S. Ranaweera, P. Sridarran, M.N.U Maddakandage*
11.00 AM - 11.15 AM	**S17091: Systematic Literature Review for Re-Defining 'Green' in Hospitality: Typology-Sensitive Interpretations** *I.R. Wijesuriya, B.A.K.S. Perera, C.C. Abenayake*
11.15 AM - 11.30 AM	**S17119: Enhancing Sustainability in Renovation Projects: The Roles of the Contractor and Consultant** *R. Jathurshan, K.G.A.S. Waidyasekara, H.C. Victar, M.M.N. Mannapperuma*
11.30 AM - 11.45 AM	**S17121: Criteria for Selecting Retrofitting Options for HVAC Systems in Sri Lankan Commercial Buildings** *G.N.T.J. Bandara, Sachie Gunatilake, Dasuni Kodituwakku*
11.45 AM - 12.00 NOON	**Q&A**

Session Coordinator: Ms. Dewmini Wijerathne

SATURDAY, 16 AUGUST 2025

SESSION 4E

Theme	**Optimising Public Procurement through Social Value and Competency**
Session Chairs	**Ch. QS Vijitha Disaratna**
Venue/Time	**Room E - 10.30 AM – 12.00 NOON**
Virtual	**Breakout Room - Session E**

Time	Paper ID, Title and Author(s)
10.30 AM - 10.45 AM	**S17026: Integration of the Concept of Social Procurement into Construction Procurement in Sri Lanka** *Malintha H. Fernando, B.A.K.S. Perera*
10.45 AM - 11.00 AM	**S17065: Shaping Successful Procurement Futures: The Evolving Landscape of Public-Private Partnerships in Sri Lanka** *G. Fernando, C. Hadiwattege, M. Thayaparan, U. Kulathunga*
11.00 AM - 11.15 AM	**S17066: Establishing Schedule Quality Parameters for Effective Delay Analysis in Construction Projects** *Sneha Baskar, Murali Jagannathan, Dheeraj K Ubhayakar, K Hariharan*
11.15 AM - 11.30 AM	**S17093: Competency Requirement for Professionals Involved in Public Construction Procurement Process: A Review** *S.S. Weerathunge, K.A.T.O. Ranadewa*
11.30 AM - 11.45 AM	**T17106: Developing a Knowledge Value Chain Framework for Tendering in Sri Lankan Construction Organizations** *Lebunu Hewage Udara Willhelm Abeydeera, Jayantha Wadu Mesthrige, A.S.W. Karunarathna*
11.45 AM - 12.00 NOON	**Q&A**

Session Coordinator: Ms. Nishadi Nanayakkara

CHIEF GUEST

Emeritus Prof. Malik Ranasinghe

Emeritus Professor,
University of Moratuwa, Sri Lanka

Professor Malik Ranasinghe is an Emeritus Professor at the University of Moratuwa and the Vice President of the National Academy of Sciences Sri Lanka. He is a Chartered Engineer and Fellow of the Institution of Engineers, Sri Lanka, Fellow of the National Academy of Sciences, Sri Lanka, Fellow of the Institute of Project Managers, Sri Lanka and Graduate Member of Sri Lanka Institute of Directors.

Prof. Ranasinghe graduated with BSc Eng, (Hons). in Civil Engineering from the University of Moratuwa and obtained his MSc in 1987 and PhD in 1990 from the University of British Columbia, Vancouver, Canada in Civil Engineering Economics as a Canadian Commonwealth Scholar. He was awarded the DSc (Honoris Causa) by the University of Moratuwa, Sri Lanka in 2024. Prof. Ranasinghe's research focus is to combine civil engineering economics, risk analysis and environmental economics with project management. He has published over 145 research publications, of which 79 are international refereed publications. His Hirsch Index (h-Index) is 19 and he is a Sri Lanka Tier 4* researcher.

Prof. Ranasinghe is the former Vice Chancellor of the University of Moratuwa, and former Chairman of the Information and Communication Technology Agency (ICTA) of Sri Lanka, He is former Chairman of the Committee of Vice-Chancellors and Directors of Sri Lanka, Commission Member of the University Grants Commission, Council Member of the National Research Council, Council Member of the Association of Commonwealth Universities (ACU), former Dean of the Faculty of Engineering, and Chairman, Centre of Excellence in Project Management at the University of Moratuwa. He is a former Fellow of the National University of Singapore. Prof. Ranasinghe has also been involved with the corporate sector in Sri Lanka since 2003. He is an independent non-executive Director of Pan Asia Bank PLC and ACL Cables PLC, former Chairman of Sampath Bank PLC, and former independent non-executive Director of Access Engineering PLC, Resus Energy PLC, Teejay Lanka PLC, United Motors Lanka PLC, Sampath Bank PLC, Hemas Power PLC, Lanka IOC PLC, and the Colombo Stock Exchange.

KEYNOTE SPEAKERS

Prof. David Proverbs

Associate Pro Vice-Chancellor for Enterprise and Business Innovation,
De Montfort University, United Kingdom

Keynote on 'Building Resilient Communities: Lessons from the UK Flood and Coastal Resilience Innovation Programme (FCRIP)'

Professor David Proverbs is Associate Pro Vice-Chancellor for Enterprise and Business Innovation at De Montfort University, responsible for developing the knowledge exchange strategy. He has over 30 years of experience in higher education and held strategic leadership roles in four modern universities. He is passionate about the environment, a great believer in the benefits of working in a global society and committed to creating opportunities for our students to become global, climate aware citizens. He has developed significant regional, national and international research and enterprise collaborations drawing on a range of funding sources to pioneer innovative solutions towards improving resilience to flooding. His research has had significant national and international impact in the development of UK Climate Change Policy; as lead innovation adviser to the Environment Agency's Trent Regional Flood and Coastal Committee; and through supporting the development of national flood risk strategies, for example in Brazil, China, Nigeria, Peru and the UK. He is Editor in Chief for the International Journal of Building Pathology and Adaptation and the Journal of Flood Risk Management.

KEYNOTE SPEAKERS

Prof. Srinath Perera

Chair Professor of Built Environment and Construction Management, Founding Director - Centre for Smart Modern Construction (c4SMC), Western Sydney University, Australia

Keynote on 'Sustainability and Circularity through Digitalisation'

Professor Srinath Perera is the Chair Professor of Built Environment and Construction Management and Founding Director of the Centre for Smart Modern Construction (c4SMC) at Western Sydney University. He is President of AUBEA, Chair of the CIB Future Leaders Committee, and Founding Chair of the CIB Doctoral School. He also serves as Editor-in-Chief of Construction Innovation (Q1) and Specialty Editor-in-Chief of Frontiers Blockchain (Industry). A pioneer in construction informatics, Professor Perera integrates AI, Blockchain, IoT, BIM, Digital Twins, and sustainability into construction and project management. He has authored over 300 peer-reviewed publications and led major research initiatives, including securing over $700k in industry funding and participating as Chief Investigator in ARC grants exceeding $30 million. He currently holds a national grant to develop a digitalisation policy for the construction industry. He is a Fellow of the Royal Society of NSW and the Australian Institute of Building, and a Chartered Surveyor affiliated with RICS, AIQS, and AIPM. With over 30 years' experience in academia and industry, he has been recognised with awards such as the AIB Professional Excellence Awards (2019, 2024) and the 2024 Vice Chancellor's Award for Excellence in Postgraduate Supervision. His work continues to shape innovation and leadership in the built environment sector.

PANEL DISCUSSION

Panel Discussion on '2030 Step Ahead: Strategic Foresight for the Sri Lankan Construction Industry'

Panel Members	**:**	Prof. David Proverbs Prof. Srinath Perera Prof. Chithra Weddikkara Dr. Rohan Karunaratne Dr. Kalana Alwis
Panel Moderator	:	Ch.QS. Lalith Ratnayake
Thematic Summary Contributor	:	Dr. Suranga Jayasena

Panel Member

Prof. David Proverbs

BSc (Hons), PG Cert-Ed, PhD, MBA, PFHEA, FCIOB, FRICS
Associate Pro Vice-Chancellor for Enterprise and Business Innovation
De Montfort University, United Kingdom

Panel Member

Prof. Chithra Weddikkara

BSc (BE), A. Arch. (Aust), B. App. Q.S. (Distcnt.) (Aus), MSc. Build. (Aus.),
PhD Law (Aus), FRICS, ARAIA, AAIQS FIA (SL), FIQS (SL) IPMSL
Emeritus Professor, Department of Building Economics, University of Moratuwa

Prof. Chitra Weddikkara is a globally respected authority in building economics and quantity surveying with over three decades of leadership in Sri Lanka's built environment sector. As a former Head of the Department of Building Economics and former Dean of the Faculty of Architecture at the University of Moratuwa, she guided the establishment of undergraduate and postgraduate programmes including Quantity Surveying, Facilities Management, Project Management, and Dispute Resolution and Law. Her influence extends to academia and professional governance: she is a Chartered Quantity Surveyor and Architect, and holds fellowships with RICS, AIQS, IQSSL and FIPMSL. Prof. Weddikkara has served as President of the Institute of Quantity Surveyors Sri Lanka (IQSSL), the Sri Lanka Institute of Architects (SLIA), and Commonwealth Association of Surveyors and Land Economists (CASLE). She has also held leadership roles with CIDA, ICTAD, RICS Sri Lanka, and the Green Building Council Sri Lanka.

Panel Member

Dr. Rohan Karunaratne

B.E (India), T.Eng. (CEI), MIE (Lon.), MBA (UK), FIIM (HK), FCIOB (Ceylon), PhD (USA)
President, Ceylon Institute of Builders (CIOB)

Dr. Rohan Karunaratne is a distinguished engineer, entrepreneur, and industry leader with an exceptional track record in construction, finance, and corporate governance across South Asia. Holding a B.E. from India, an MBA from the UK, and a Ph.D. from the USA, he is also a Chartered Engineer and a Fellow of multiple international professional bodies. He currently advises the Ministry of Justice, Prison Affairs and Constitutional Reforms and the Export Development Board and serves in the SAARC General Assembly. Dr. Karunaratne chairs several initiatives, including Human Resource Development, the Overseas Training Academy, and the South Asian Lean Construction Association, where he is President. His leadership portfolio includes serving as President of the Ceylon Institute of Builders (CIOB) and the Chamber of Construction Industry (Vice President), as well as Past President of the National Construction Association of Sri Lanka. In the corporate sector, he has chaired or directed multiple organisations, from AKK Engineers and Arpico Finance to Hatton National Bank and Sino Lanka Hotels and Spa. Renowned for championing lean construction, sustainable industry practices, and cross-border collaboration, Dr. Karunaratne brings with him a wealth of expertise and vision.

Panel Member

Dr. Kalana Alwis

D.Eng. (USA)
Director/Chief Executive Officer
Nawaloka Construction Company (Pvt) Ltd.

Dr. Kalana Alwis, D.Eng. (USA), is a distinguished civil engineer and business leader with over 40 years of experience in Sri Lanka's construction industry. Starting his career at the Department of Irrigation, he joined Nawaloka Construction Company in 1985 and rose to become its Director/Chief Executive Officer. Under his leadership, the company achieved ISO 9001:2015, ISO 14001:2015, and OHSAS 45001:2018 certifications, expanding its presence in high-rise, highway, heavy construction, and design-and-build projects locally and internationally. In recognition of his contributions, the American National Business University, USA, awarded him the title of Doctor of Engineering Management in 2022. He holds key leadership roles in the industry, including Chairman of Engineering & Construction at the National Chamber of Commerce of Sri Lanka, Vice President of the Major Constructors of Sri Lanka, the Ceylon Institute of Builders and Vice Chairman of Major and Specialist Constructors of Sri Lanka. He is also a Council Member of the Chamber of Construction Industry and the Advisory Committee Member of the Sri Lanka Export Development Board. His leadership extends internationally through his role on the Executive Committee of the Consulate of the Republic of Philippines in Colombo. Throughout his career, Dr. Alwis has not only elevated his company's industry standing but also brought pride to his alma mater, Rahula Vidyalaya, Matara.

Panel Moderator

Ch.QS Lalith Ratnayake

M.Sc. (PM), B.Sc. (Hons) QS, F.I.Q.S.SL
Contract Management Consultant, Director, VFORM Consultants Private Ltd.

Chartered Quantity Surveyor Mr. Lalith Ratnayake is one of the founders of VFORM Consultants Private Limited. He has experience in both building and infrastructure projects locally and overseas. His experience includes Contracts Management/Contracts Administration, Quantity Surveying (QS), Project Management, QS Service Outsourcing, Technical Audits, Claims Management and Dispute Management Services of many medium and large-scale projects. He is the Past president of the Institute of Quantity Surveyors Sri Lanka (IQSSL). Mr. Lalith Ratnayake has been a visiting lecturer for B.Sc. QS programme for more than 15 years and M.Sc. Construction and Law and Dispute Resolution programme, at University of Moratuwa for the contract interpretation and claims management subjects. He is a contributor to a large number of research projects and has published many technical papers. The vast practice experience, high involvements in professional activities, unremitting industry interactions and continued exposure to academic activities made him a much sought after professional in the construction sector. Also Mr. Rathnayake is an accredited mediator.

Thematic Summary Contributor

Dr. Suranga Jayasena

PhD, MSc (Building), BSc (Hons) QS, FIQSSL
Senior Lecturer, Department of Building Economics, University of Moratuwa

Ch. QS. Dr. Suranga Jayasena is a former head of the Department of Building Economics, University of Moratuwa and currently serving as a Senior Lecturer of the Department. He obtained a B.Sc. (Hons) degree in Quantity Surveying from the University of Moratuwa and an M.Sc. in Building from the National University of Singapore. In 2023, Dr. Jayasena completed his PhD at the University of Moratuwa, Sri Lanka. While his primary teaching area is Building Procurement, his research interests span a broader landscape, encompassing Building Economics, Procurement Systems, Dispute Resolution, and Construction Information Technology, all of which are intertwined with Building Procurement and enrich his teaching. He is a Fellow, a member of the governing council, and a Committee Chair of the Institute of Quantity Surveyors Sri Lanka (IQSSL).

A BIBLIOMETRIC ANALYSIS OF COMPUTER VISION APPLICATIONS IN CONSTRUCTION AND DEMOLITION WASTE MANAGEMENT

A.S.W. Karunarathna[1] and G.G.N. Chandani[2]

ABSTRACT

With approximately 10 billion tonnes of construction and demolition waste produced yearly, the construction sector is the biggest producer of solid waste, which accounts for 40% of urban solid waste that contributes to serious environmental issues, including soil degradation, resource depletion, and an excessive dependence on landfilling. Introduction of new avenues towards addressing these issues has been facilitated by recent advancements in computer vision that have yielded efficient, self-sustaining, and prudent construction and demolition waste management. The objective of this study is to conduct a rigorous bibliometric analysis to examine the role of computer vision towards improved construction and demolition waste management. This study will identify the growth of the research area, top contributing sources, and collaboration patterns. A bibliometric approach was employed to evaluate 29 peer-reviewed journal articles and conference proceedings between 2015 and 2025. Organized keyword searching to obtain information from Scopus and Web of Science was employed. Manual analysis was done for identifying publication patterns, top sources, and country output. Keyword co-occurrence and collaboration network analysis were done using VOS viewer software. Although computer vision techniques, including semantic segmentation, object detection, and deep learning, have been promising in recycling and waste sorting automation, existing literature is fragmented. Most studies are focused on a single application, without the extraction of broader trends or collaborative dynamics. The paper provides an integrated corpus of knowledge for researchers, practitioners, and policymakers by presenting an exhaustive bibliometric analysis that documents the historical patterns of computer vision in construction and demolition waste research.

Keywords: *Bibliometric Analysis; Construction and Demolition Waste; Computer Vision; VOS viewer; Waste Management.*

1. INTRODUCTION

The construction industry is a significant contributor to global CO_2 emissions and the world's largest producer of waste (Driouache et al., 2024). Due to the accelerated global urbanisation, the annual production of construction and demolition waste (CDW) surpasses 10 billion tonnes, accounting for up to 40% of total solid waste (Prasad &

[1] Lecturer (Temporary), Department of Facilities Management, University of Moratuwa, Sri Lanka, sandunik@uom.lk
[2] Lecturer (Temporary), Department of Facilities Management, University of Moratuwa, Sri Lanka, navodag@uom.lk

Arashpour, 2025), rendering it the most common type of urban solid waste (Wu et al., 2024). Moreover, CDW is one of the most significant energy consumers during the construction process (Gong et al., 2024). Inadequate management and disposal of CDW may result in significant environmental deterioration, including soil pollution, resource depletion, excessive landfill usage, and increased greenhouse gas emissions (Prasad & Arashpour, 2024b). Therefore, the efficient and sustainable handling of CDW has become a significant concern for stakeholders and regulators.

Over the past years, Computer Vision (CV) has been an emerging technology, proving itself capable of resolving challenging issues related to the management of CDW. CV is a field that focuses on enabling machines to interpret and understand visual information from the world, primarily through the analysis of images and videos (Sirimewan et al., 2024). CV revolutionises the administration of CDW by automating, precisely, and efficiently, the processes of identifying, classifying, and separating waste (Sun & Gu, 2022). Advanced techniques such as semantic segmentation (Lu et al., 2022), object detection (Zhou et al., 2023), and image recognition (Dong et al., 2022) enable computer vision systems to interpret complex and mixed detritus structures in real time. This process of automation not only significantly improves the efficacy and accuracy of material recovery processes, but it also reduces the need for human labour, thereby preventing health and safety issues (Ji et al., 2024). Further to the authors, in conjunction with automation solutions and deep learning platforms, CV enables intelligent decision-making along waste sorting lines, resulting in optimal recycling rates, reduced processing costs, and sustainable construction practices.

Despite this technological enthusiasm, the literature illustrates a non-linear and fragmented progression in the development of research in CV applications for CDW. Several studies have examined single-use cases, including the classification of recyclable images (Dong et al., 2022), the detection of objects for robotic categorisation (Wang et al., 2024), and the use of semantic segmentation (Lu et al., 2022) in waste management. However, these contributions frequently continue in their isolation, lacking a comprehensive synthesis of research trends, development paths, and collaboration networks. Therefore, this paper conducts a thorough bibliometric analysis of scholarly research on CV applications in CDW management to address this critical gap. The objective of this study is to conduct a comprehensive review of the current literature on CV in CDW to establish a comprehensive foundation for the further development and dissemination of knowledge. As a result, the objectives of this study are the following: (i) to identify the evolutionary progression of the research field in CV in the CDW and (ii) to reveal the primary research themes in the field. The paper structure begins with an introduction to the study and followed by the research methodology and findings. The final section of the paper presents the conclusion of this research.

2. METHODOLOGY

This study employs a comprehensive methodological approach, applying bibliometric analysis to identify the sophisticated literature which is in relation to the CV in CDW management. According to (De-Oliveira et al., 2019) bibliometric analysis is a statistical instrument that is employed to represent the current state of scientific knowledge. It identifies research opportunities, trends, and voids by analysing citations, authors, institutions, countries, and journals, thereby facilitating the development of scientific projects. For the bibliometric analysis of this study, Scopus and Web of Science were

employed due to their extensive coverage of subjects and adequate quality. Additionally, they possess the largest abstract and citation database of peer-reviewed articles in comparison to the other databases (Wijewickrama, 2025). Following key terms were used as the search string with the intention of extracting as many relevant, high-quality papers as possible. ("computer vision" OR "machine vision" OR "AI vision" OR "artificial vision") AND ("construction waste" OR "demolition waste" OR "C&D waste" OR "construction and demolition waste" OR "construction debris"). These keywords were selected for their relevance to the context of this study, with the objective of presenting a comprehensive overview of the trends and patterns in the expanding research on CV in CDW. This syntax was subsequently employed to search for articles in the selected databases using the search query "Article title, Abstract, Keywords."

A total of 52 records were retrieved from Scopus (42), and Web of Science (10) during the initial search of databases. The data was screened thoroughly, and 9 duplicate entries were removed to preserve the originality of the data for future analysis. Journal articles and conference papers were included in the literature search while books, book chapters and similar were excluded. Further publication years were limited to 2015-2025. Figure 1 illustrates the systematic review process.

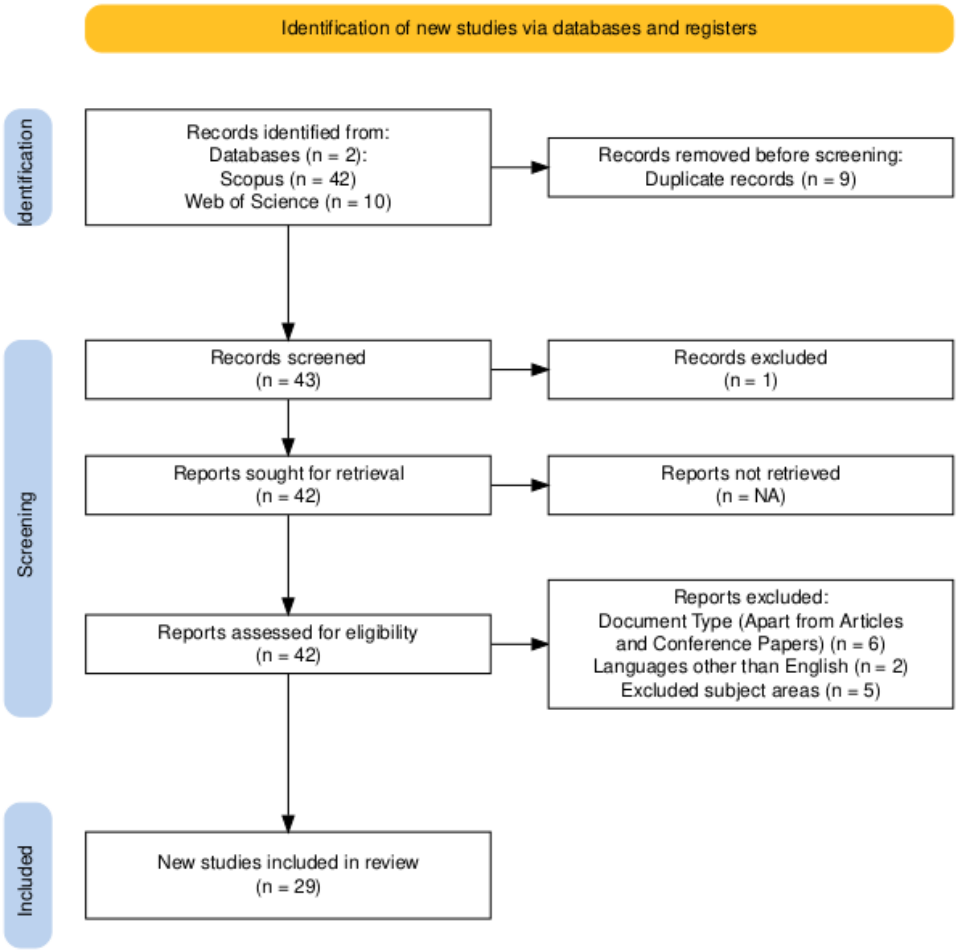

Figure 1: Systematic review process

Table 1: Inclusion and exclusion criteria

Criteria	Inclusion criteria	Exclusion criteria
Year	Publication years from 2015-2025	Publications before 2015
Document Type	Articles and Conference Papers	Books, Book chapters, reviews, notes, and editorial
Language	English language	Languages other than English
Subject Areas	Engineering, computer science, decision science, environmental science, energy, multidisciplinary	All the other subject areas

After applying the inclusion and exclusion criteria mentioned in Table 1, 29 papers from the search via databases were chosen for the analysis. This study conducted a variety of bibliometric studies using both manual techniques and VOS viewer software (version 1.6.20). The manual study concentrated on examining yearly publishing patterns and identifying the most impactful journals and conferences in the sector. Additionally, keyword co-occurrence analysis was conducted using VOS viewer to reveal significant research topics and emerging areas of interest. It also enabled the identification of prominent countries contributing to the field, as well as their patterns of international collaboration. These analyses jointly facilitated a qualitative interpretation of the bibliometric data, providing significant insights into the developing research landscape of CV in the context of CDW management.

3. RESULTS AND DISCUSSION

This section presents the results of the bibliometric analysis with relevant interpretations while addressing the objective of the study.

3.1 EVOLUTION OF PUBLICATIONS AND TOP CONTRIBUTING SOURCES

Figure 2 represents the yearly publication with related to the CV in CDW management from 2015-2025.

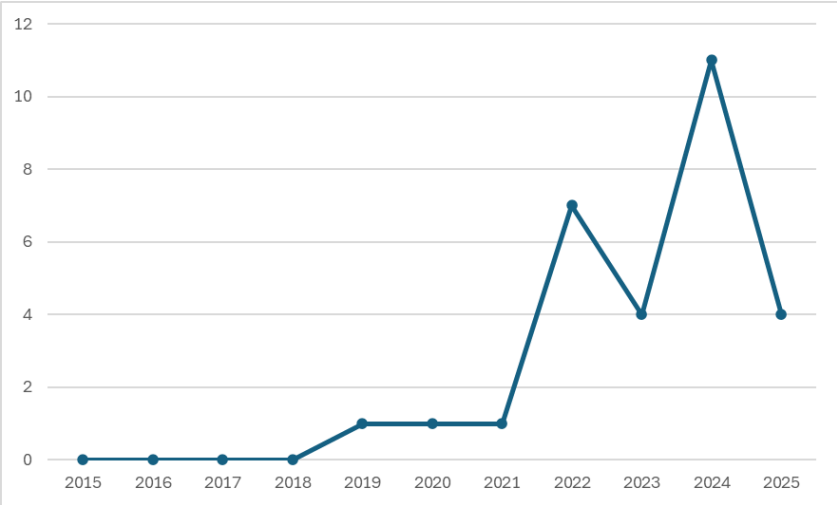

Figure 2: Publication distribution through 2015-2025

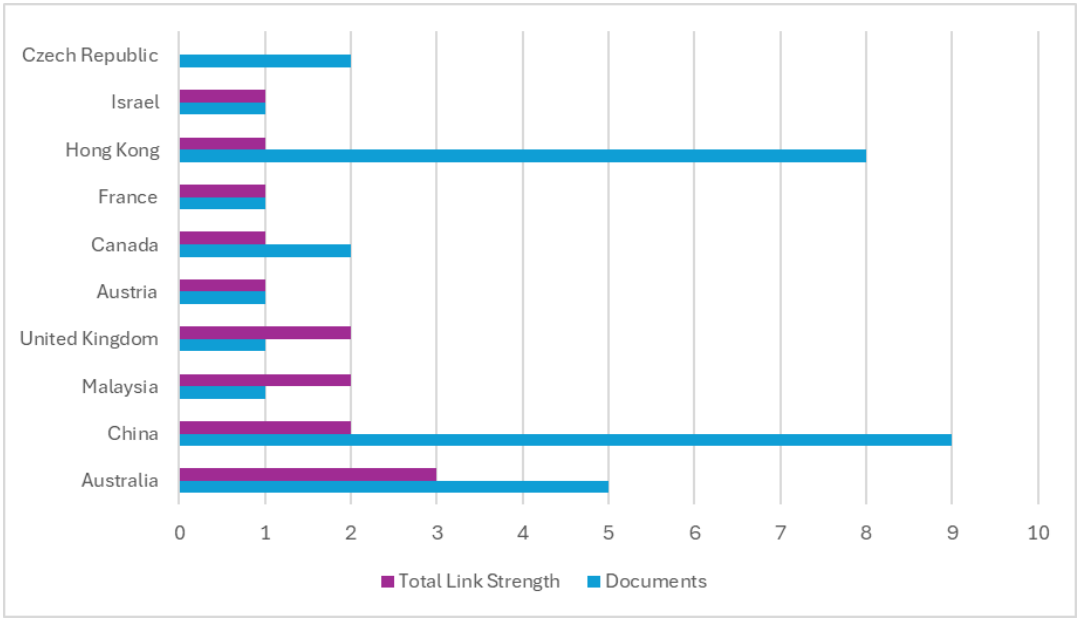
An analysis of research development patterns over the last 11 years was conducted based on the reviewed literature. According to Figure 2, there were no relevant publications concerning the chosen issue for the first four years of the specified time frame, 2015-2018. During 2019-2021 the publications remained constantly low. However, it is noticeable that there has been a gradual increase in research on computer vision in C&DW management over the past four years. This subject has attracted the attention of researchers, particularly in the years 2021–2022 increasing the publications from one to six, when it experienced a 600% rapid growth. In 2024, output reached a peak of 11 publications, exceeding the significant increase seen in 2022 by more than double. This indicates that computer vision has offered a practical solution to practical challenges in the administration of C&DW, including the generation, collection, transportation, and disposal stages. According to Wu et al. (2025), the rise in publications after 2021 is attributed to increased urbanisation, progress in intelligent technologies such as AI and computer vision, and an increasing focus on sustainable practices in the management of building and demolition waste, tackling complex difficulties within the industry. Given that merely four months have elapsed in 2025, and four publications have already been documented, it is reasonable to predict that the overall number of publications by year-end may near 12, contingent upon a steady publishing pace for the remaining months.

Table 2: Top contributing sources

Source Name	No of Articles
Journal of Environmental Management (Q1)	5
Resources, Conservation and Recycling (Q1)	5
Waste Management (Q1)	4
Sustainability (Switzerland) (Q2)	2
Buildings (Q2)	1

Table 2 shows the top five contributing sources of publication that have substantially contributed to advancing the area of study, publishing nearly 58% of the articles. The highest number of articles has been published by the Journal of Environmental Management (5) and Resources, Conservation and Recycling (5) followed by Waste Management (4). Even though most articles are published in journals related to waste management discipline, sources related to computer science and technology provide a substantial contribution to the knowledge in this area, providing a multidisciplinary nature to the concept.



3.2 LEADING COUNTRIES UNDERTAKING RESEARCH ON CV IN CDW MANAGEMENT

Figure 3 indicates the top countries and their collaborative networks in advancing research on CV in CDW management. In Figure 3(a), circle sizes in the image likely indicate the quantity of publications, and lines between circles indicate the strength of collaborative ties. The analysis reveals Hong Kong and China as top contributors with 8 and 9 documents respectively, proving their high level of scholarly contribution. Australia also contributes at a high level with 5 documents and a link strength total of 3, proving an active contribution. Even so, countries like Austria, Canada, and France, though contributing fewer documents, prove the diversity of global interest in CV in CDW research. This difference indicates varying degrees of interaction and collaboration

between countries to advance CV research in the CDW management in the examination of collaborative activity across countries in the CV within the CDW research for the construction sector, Australia (total link strength of 3) and China (total link strength of 2) demonstrate the most significant level of collaborative linkages. The United Kingdom and Malaysia also demonstrate strong participation, with a link strength of 2, to signify their active engagement in international collaborative research efforts. While Hong Kong has a high document output of 8, a comparatively low link strength of 1 would suggest a more solo approach to research among its collaborative partners. Notably, developing nations such as Malaysia and China are well represented in collaborative research efforts. The presence of these countries along with developed nations such as Australia and the UK indicates an even contribution based on economic status. However, some countries with high scholarly contribution, such as the United States and Japan, indicate minimal cooperation (link strength of 0), indicating an independent research approach. This contrast highlights divergent strategies in CV in CDW research participation, with some nations focusing on partnerships while others focus on individual initiatives. The active co-operation of rising nations such as China and Malaysia, despite challenges, reflects their growing influence and role towards the advancement of CV research in the construction sector.

(a)

(b)

Figure 3: Representations of prominent countries and their collaborative networks in advancing research on CV in CDW management.

3.3 KEY WORD CO-OCCURRENCE

Figure 4 illustrates the results of the analysis conducted using VOS viewer software, with a minimum threshold of two occurrences for keywords. In the network, the diameter of each circle represents the frequency of the term, while the thickness of the connecting lines denotes the strength of the association between the keywords. Furthermore, the closeness of nodes demonstrates the extent of linkage, with nearer nodes indicating more closely connected phrases. Keyword co-occurrence analysis is essential in academic research as it illustrates linkages between study subjects, uncovers temporal patterns, and assists researchers in comprehending the development of knowledge domains, hence informing future research paths (Zhao, 2024). Due to the associated search string, construction and demolition waste and computer vision appear as the most occurred keywords.

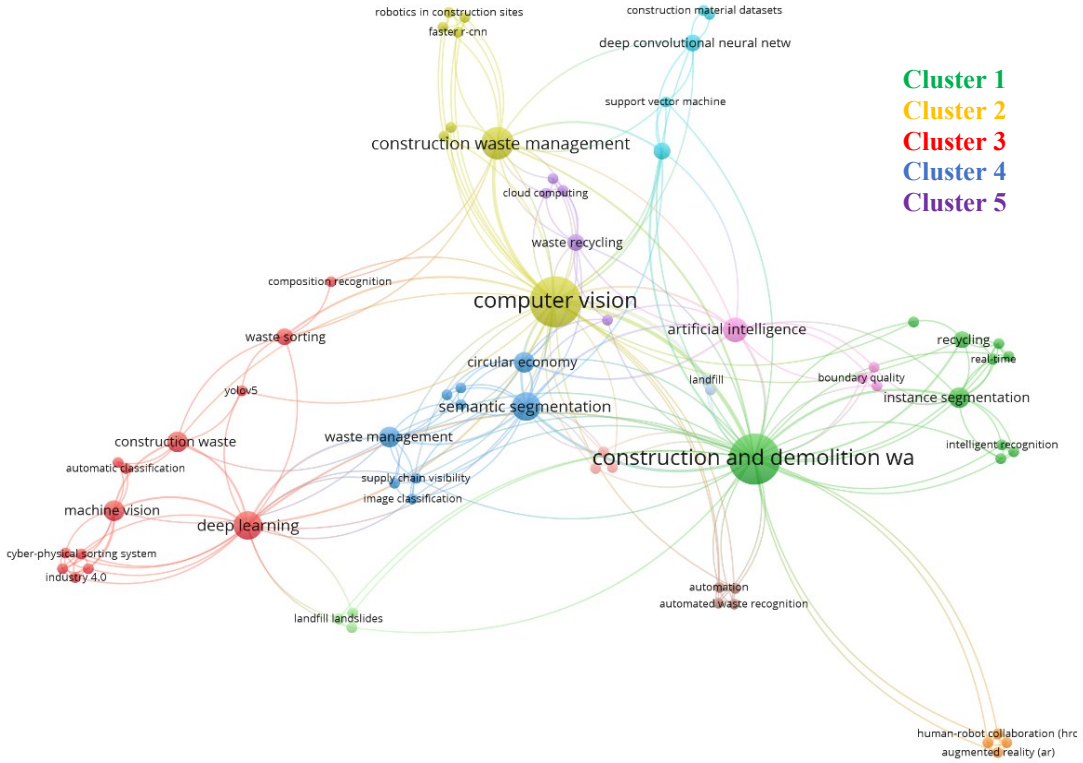


Figure 4: Key words co-occurrence analysis

The network visualisation identifies five separate research clusters in computer vision applications for construction waste management. Cluster 1 focuses on practical applications such as recycling, instance segmentation, and intelligent detection, establishing a domain-specific basis. Cluster 2 functions as a technology nexus, integrating visual analytic capabilities with waste management methodologies using technologies such as Faster R-CNN and computer vision. Cluster 3 includes sophisticated computational techniques such as YOLOv5, deep learning, automated classification, machine vision, Industry 4.0 and cyber-physical sorting systems designed for construction waste issues. Cluster 4 highlights image usage for accurate material identification across supply chains and a focus was gained in circular economy concept, whereas cluster 5 encompasses specialised neural architectures and machine learning

methodologies that facilitate these applications such as cloud computing and AI. Cross-cluster interaction is most intense at the intersections of technological advancement and practical application. The strong connections between deep learning and construction waste clusters illustrate the targeted optimisation of AI algorithms for waste material detection, while the linkages between computer vision and semantic segmentation indicate the integration of methodologies across AI fields. The integration of circular economy principles across several sectors emphasises the role of sustainability frameworks in encouraging technological innovation. Emerging domains such as human-robot cooperation and augmented reality at the network perimeter indicate new multidisciplinary frontiers where physical and digital technology intersect. The collaborative patterns illustrate a research ecosystem in which computer researchers, environmental engineers, and construction management specialists collaborate to create advanced waste management solutions that integrate visual intelligence with domain knowledge.

3.4 APPLICATION OF CV IN CDW MANAGEMENT

The CDW management faces several challenges due to waste volume and environmental impact (Sirimewan et al., 2024) such as illegal disposal, costly recycling, transportation challenges, and inadequate treatment facilities (Mager et al., 2025). Further to the author, the enforcement of policy directives such as the European Union's Waste Framework Directive is obstructed by inadequate resources and inappropriate attitudes towards products derived from recycled materials. The workers' health is also at risk when manually segregating, which is why there is an inclination to automate the process. Additionally, manual sorting methods are labour-intensive and inefficient (Chen et al., 2023) and these complexities highlight the importance of automating waste recognition and handling processes and technological advancements like CV and AI.

Recent advancements in deep learning and CV have revolutionized waste management, particularly in the identification, classification, and segregation of CDW (Wang et al., 2020; Yong et al., 2023). Advanced architectures like convolutional neural networks (CNNs), Mask R-CNN, U-Net, and DeepLabv3+ enable highly accurate waste detection and segmentation, significantly improving sorting and recycling processes (Sirimewan et al., 2024). These technologies have been successfully applied in various specialized applications, including semantic segmentation models like DeepLabv3+ and PromSeg-Waste (Sirimewan et al., 2024; Wang et al., 2020) that provide pixel-level accuracy for material identification, hybrid optical-physical systems (Chen et al., 2021) that enhance composition analysis in material recovery facilities, and real-time detection systems using YOLOv5 and vision transformers (Chen et al., 2022; Yong et al., 2023) that facilitate instant trash classification. Further innovations such as instance segmentation combined with Simultaneous Localization and Mapping (SLAM) technologies (Dong et al., 2025; Wang et al., 2020) improve trash detection in complex environments, while RGB-D data integration enhances object boundary detection for robotic sorting systems (Prasad & Arashpour, 2025). Together, these technological advancements reduce reliance on manual sorting, gradually improve recycling efficiency, and support more sustainable waste management practices. When integrated with Industry 4.0 principles, the integration of automated sorting systems, enhanced by artificial intelligence and machine vision, allows for efficient classification and recycling of materials, thereby reducing waste and promoting resource recovery (Konstantinidis et al., 2023; Prasad & Arashpour, 2024a). These systems, such as Cyber-Physical Sorting Systems (CPSS), utilize multi-

spectral imaging and deep learning to improve the accuracy of material identification, which is crucial for effective recycling (Konstantinidis et al., 2023). Furthermore, the application of Industry 4.0 principles facilitates the development of intelligent waste management solutions that can adapt to various waste types, ultimately supporting sustainable practices and reducing the environmental impact of CDW activities (Driouache et al., 2024; Nežerka et al., 2024). Table 3 demonstrates a summary of the selected articles for the study.

Table 3: Summary of the literature findings

Author	Type of model used	Usage	Dataset Size	Accuracy	Waste Type
Sirimewan et al., 2024	PromSeg-Waste model	Waste segmentation	5277 image-mask pairs corresponding to ten distinct waste classes	9% increase compared to the existing SOTA model	Concrete, Fill dirt, Wood, Hard plastic, Soft plastic, Steel, Fabric, Cardboard, Plasterboard, Glass
Konstantinidis et al., 2023	Cyber-Physical Sorting System (CPSS)	use of multi-sensor systems for real-time material classification and sorting	171 images, with 41.5% being plastic and 27.5% metal of urban-based samples from commercially available materials	80% detection accuracy	Glass, Metal, Paper, Plastic
Nežerka et al., 2024	Gradient boosting, multi-layer perception, Convolutional neural network	Waste recognition and sorting	2664 nos. of 1920 × 1280 px images of ∼30–250 mm fragments distance of about 70 cm	GB-92.3%; MLP-91.3%; CNN-85.9%	Light-coloured Aerated Autoclaved Concrete (AAC), Asphalt conglomerates, Ceramics (Roof Tiles and Bricks), Concrete
Dong et al., 2025	17 models including BEiT; DeepLab V3; OCRNet; FastFCN etc	Waste sorting	4396 common local construction waste images	Highest accuracy BEiT model with 58.31% accuracy	Rock, Gravel, Earth, Packaging; Wood, Non-inter; Mixed
Zhou et al., 2023	YOLOv5	Object detection and waste sorting	3046 construction waste images	0.9480 precision on the test dataset	Brick, Wood, Stone, Plastic

Author	Type of model used	Usage	Dataset Size	Accuracy	Waste Type
Lu et al., 2022	DeepLabv3+	Semantic segmentation approach for CW composition recognition	5,366 images	mean Intersection over Union (mIoU) of 0.56 for segmenting construction waste materials	Inert and non-inert waste
Mager et al., 2025	Segment Anything Model (SAM) and ResNet-50	Aerial image analysis for illegal construction waste	46,000+ manually labelled masks	86% (area classification), 67% (mask classification)	Mixed waste
Chen et al., 2022	Monocular vision-based volume estimation algorithm	Automatic quantification of material volumes	2,914 waste truckloads analyzed	Relative error: 0.065 (bucket size), 0.169 (material-level volume); Processing time: 3.3s/image	Rock, Gravel, Earth, Packaging, Wood, Non-inter, Mixed
Dong et al., 2022	Boundary-aware Transformer (BAT) with cascade decoder and edge refinement	Semantic segmentation of different waste materials in cluttered mixtures	5366 photos of highly cluttered construction waste mixtures	69.19% Mean Accuracy	Rock, Gravel, Earth, Packaging, Wood, Non-inter, Mixed
Prasad & Arashpour, 2025	ShARP-WasteSeg: Shape-Aware Real-Time Precise Waste Segmentation (multi-modal with RGB + depth)	Real-time instance segmentation using boundary and shape info for cluttered CDW objects	3568 high-definition colour and depth images	ShARP-WasteSeg improved Mask Average Precision (AP) by 7.91%, and the boundary-sensitive Boundary Average Precision by a significant 11.44%	Aggregate, Cardboard, Hard plastic (HDPE), Metal, Soft plastic (LDPE), Timber
Yong et al., 2023	DeepLabV3+	Semantic segmentation of remote sensing	Case study in Shenzhen (52 landfills identified)	96.30% accuracy	Landfills

Author	Type of model used	Usage	Dataset Size	Accuracy	Waste Type
		imagery to detect CDW landfills			
Wang et al., 2024	Pixel-level recognition model with edge (YOLO-Tiny) & cloud computing integration (YOLACT)	Real-time automated recognition and instance segmentation for robotic waste sorting	Not specified	90.81% accuracy (edge), 93.2% instance segmentation accuracy (cloud)	Not specified
Prasad & Arashpour, 2024a	RGB-DL architecture with efficient depth fusion strategy	Intelligent segmentation of valuable recyclables from cluttered CDW streams	3,500+ RGB & depth images; 160,000+ labeled object instances	+13% segmentation accuracy	Aggregate, Cardboard, Hard plastic (HDPE), Metal, Soft plastic (LDPE), Timber
Prasad & Arashpour, 2024b	9 models including YOLACT++; CenterMask; CondInst; SOLOv2; RTMDet-Ins etc	Accurate, fast localization and segmentation of CDW recyclables	Not specified	+12.9% segmentation performance; +68% correct mask predictions	Aggregate, Cardboard, Hard plastic (HDPE), Metal, Soft plastic (LDPE), Timber
Driouache et al., 2024	Semantic segmentation DeepLabv3+	Identify and classify CDW materials in dump trucks before landfill entry	From the month of February 2022 to May 2022, 806 images were collected	accuracy: 99.0%; Homogeneity: 94.8%	Block, Gravel, Soil, Metal

4. CONCLUSION

Sustainable CDW management is crucial due to the fact that CDW accounts for up to 40% of the total solid waste produced worldwide and poses over 10 billion tonnes of waste annually. Even though the integration of computer vision (CV) in CDW processing in the form of automation of waste identification, classification, and categorisation offers potential solutions that can lead to increased recycling efficiency and a reduced environmental burden. The growth of co-related studies was prompted by global sustainability objectives and artificial intelligence in 2021, as evidenced by bibliometric metrics. China, Hong Kong, and Australia are among the countries that have been at the forefront of academic production and collaboration on an international scale. Cluster and keyword analysis reveal five critical research areas, including semantic segmentation, circular economy convergence, cyber-physical systems, and deep learning. The

YOLOv5, Mask R-CNN, and DeepLabv3+ models were used to demonstrate real-world applications of high-precision material classification and identification. In the meanwhile, the implementation of Industry 4.0 technologies, including cyber-physical systems, has enabled the development of scalable and intelligent waste management facilities. Future research should further investigate human-CV collaboration systems and adaptable models based on transfer learning. Further, the incorporation of CV with life cycle assessment methods may improve its environmental benefits, and research on its economic feasibility will enable it to be applied to a broader range of applications. In order to ensure the equitable and effective integration of CV in CDW management, it is also necessary to develop ethical artificial intelligence and smart policy-supporting tools. In conclusion, computer vision has the potential to transform CDW management by enhancing its sustainability, intelligence, and efficiency, which is consistent with the objectives of the circular economy and the global environmental community.

A CONCEPTUAL FRAMEWORK FOR CAPACITY BUILDING IN PHYSICAL ASSET RESILIENCE

S.P. Koralage[1], P.A.D. Rajini[2] and W.K.U.R.M.K.P.K. Samarakoon[3]

ABSTRACT

Physical assets, defined as tangible resources with intrinsic value, play a major role in organisations. The concept of Physical Asset Resilience (PAR) is a physical asset's ability to prepare for, absorb, recover from, and adapt to disruptions. The resilience of physical assets is increasingly recognised as important for maintaining operational continuity and allowing long-term sustainability in the face of disruptions within the organisation. For capacity building in PAR required to develop or strengthen the four capacity building elements, including skills, resources, policies, and practices needed to enhance physical asset resilience capacities. However, the extant literature does not provide a clear picture of how capacity-building elements interactively contribute to capacity building in the PAR or how organisations currently approach PAR. Accordingly, by adopting a comprehensive literature review, this study proposes a conceptual framework for capacity building in PAR, focusing on four capacities: anticipative, absorptive, restorative, and adaptive, with their sub-elements. For instance, sub-elements in policies include the maintenance policy, communication policy, practices, including conducting physical assets risk assessments, resources, including backups, physical assets, financial resources, and finally, skills, are technical skills, maintenance skills. This proposed framework provides a structured foundation for future researchers who are in the field of PAR, and for practitioners, offering guidance for improving PAR in organisations.

Keywords: *Capacity Building; Physical Asset; Physical Asset Resilience; Physical Asset Resilience Capacity.*

1. INTRODUCTION

Physical Asset Resilience (PAR) is becoming a popular pillar of organisations. The resilience of physical assets is significant for ensuring continuous operations and minimising the impact of different disruptions, whether the disruption has arisen internally or externally (Aruväli et al., 2023). PAR is characterised by four capacities: anticipative capacity, absorptive capacity, adaptive capacity, and restorative capacity. Capacity building in PAR can be identified as a promising approach for developing these

[1] Undergraduate, Department of Facilities Management, University of Moratuwa, Sri Lanka, koralagesp.20@uom.lk
[2] Lecturer, Department of Facilities Management, University of Moratuwa, Sri Lanka, damithar@uom.lk
[3] Lecturer, Department of Facilities Management, University of Moratuwa, Sri Lanka, samarakoonk@uom.lk

capacities. In the context of PAR, capacity building refers to the development or strengthening of the skills, resources, policies, and practices to enhance PAR capacities. Despite the growing recognition of PAR's importance, the role of capacity building for the four PAR capacities remains underexplored. Existing literature does not clearly understand how skills, resources, policies, and practices contribute to strengthening PAR in business organisations. Therefore, this paper addresses this gap by proposing a conceptual framework with capacity building and four capacities of PAR. The paper is structured as follows. The next section discusses the research method, while the third and fourth sections present a thorough review of the literature and the development of the conceptual framework, respectively. Finally, the paper concludes with implications of the findings and future directions of the study.

2. RESEARCH METHODOLOGY

This study adopts a literature review to explore the existing studies related to PAR and capacity building. A literature review serves as a foundation for understanding prior work, identifying research gaps, and synthesising key concepts (Saunders et al., 2009). This study used a non-systematic literature review, which allows flexible integration of diverse studies to support conceptual development (Lilley et al., 2020). Compared to the structured systematic reviews (Snyder, 2019; Lame, 2019), this method is more suitable for exploratory research while improving the conceptual insights needed for framework development. The review focused on literature from the past 10–15 years to include both foundational and recent insights. Sources were selected based on their relevance to capacity building and physical asset resilience. It was based on a structured search of academic databases such as Scopus, ScienceDirect, along with professional platforms like Google Scholar and ResearchGate for supplementary sources. The sources included peer-reviewed journal articles, conference papers, and industry reports. The following search string was used to guide the review. "Physical Asset Resilience", “Capacity Building Elements”, “Capacity Building in PAR”. In addition, a manual content analysis technique was employed to analyse and synthesise the literature relevant to the development of the conceptual framework. The process of development of the conceptual framework for capacity building in PAR involved: (1) identifying key concepts related to PAR and capacity building from the literature, (2) identifying the relationships between these concepts, (3) organising the concepts and their relationships into a coherent conceptual structure and (4) developing the conceptual framework in a way that capacity building in PAR is easily understood. Hence, it developed solely through literature synthesis and is intended to guide future research.

3. LITERATURE REVIEW

3.1 PHYSICAL ASSET RESILIENCE

The word resilience originated from the word “resiliere”, a Latin word that denotes the bounce back (Hosseini et al., 2016; Rose, 2009). Wu et al. (2013) defined resilience as the ability to withstand in the face of disruptions, whereas Fleming and Ledogar (2008) mentioned it as the process and outcome of successfully adapting to disruptions. A physical asset is a tangible item with economic or operational value to an organisation, such as equipment, machinery, tools, infrastructure, or inventory (Hayes, 2022). These assets form the backbone of organisation operations, supporting efficiency, productivity,

and organisational success (Schuman & Brent, 2005; Trojanowski, 2015). However, physical assets are also faced with various disruptions, such as breakdowns, natural disasters, deterioration, operational disruptions, and unexpected external conditions (Gardoni et al., 2021; Heckmann et al., 2015; Linkov et al., 2013), and therefore, PAR has become a fundamental component in a business organisation's operations (Madni et al., 2020). The concept of PAR has been defined by researchers from different perspectives, reflecting several ranges of characteristics. The primary focus of the PAR is emphasising the ability of physical assets to withstand disruptions. For instance, a return to the previously designed condition or state of the physical assets after a disruption can be made by PAR (Norris et al., 2007). PAR refers to the ability of these systems to withstand, adapt to, and recover from disruptions, including natural disasters and other adverse events. In contrast, Ayyub (2013) demonstrated that the "PAR notionally means the ability to prepare for and adapt to changing conditions and withstand and recover rapidly from disruptions". These retrievals, PAR, is beyond the bounce back or return to their original state. A broader perspective incorporates preparedness and adaptability. On the other hand, recognising that PAR involves absorbing potential disruptions. Further, highlights the importance of not only withstanding disruptions but also needing efficient restoration of functionality. Hence, the above definitions highlight the common and distinct characteristics of PAR, which can be defined as the capacity of a physical asset to anticipate, absorb, recover, and adapt from disruptions. PAR helps organisations to maintain operations continuously even within disruptive conditions. Correspondingly, PAR allows organisations to adapt to external disruptions like economic fluctuations, ensuring that assets continue to support operational continuity. Besides, PAR can lead to financial achievements (Beemsterboer, 2023). Simultaneously, resilient physical assets can recover more quickly after disruptions, minimising downtime and associated financial losses (Coffee, 2019). On the other hand, resilient physical assets can enhance the overall value of physical assets, thus, organisations often willing to pay a premium for physical assets that are less likely to incur damage from disruptions, thereby increasing the market value of these physical assets (Coffee, 2019). Monitoring physical assets before disruptions and understanding their impacts helps identify vulnerabilities and inform measures for improving resilience (Asia Pacific Economic Cooperation [APEC], 2009). Accordingly, by understanding the potential risks, business organisations can introduce mitigation strategies such as maintenance, repair, retrofitting, and recovery activities (Gardoni et al., 2021; Silva et al., 2024). Similarly, PAR also facilitates effective risk management by supporting the implementation of appropriate mitigation techniques. These actions reduce the vulnerability of physical assets to future disruptions and enhance their ability to recover from disruptions (Gardoni et al., 2021). On the other hand, organisations increasingly needed to adhere to standards and regulations based on physical asset resilience (Costella et al., 2017). Therefore, by incorporating resilience into the physical asset management, organisations can ensure compliance with these regulations while also indicating transparency and accountability to the organisation's stakeholders.

3.2 PHYSICAL ASSET RESILIENCE CAPACITY OF AN ORGANISATION

According to Brown et al. (2001), capacity is the ability to obtain the stated objectives. Simultaneously, capacity can be defined as the combination of resources, skills, and abilities that allow organisations to effectively respond to and recover from disruptions (Albright & Crow, 2021). Further, it is an exclusive concept (Brown et al., 2001).

However, prior research has identified and explored various capacities associated with PAR, highlighting their significance in the ability of assets to withstand, adapt, absorb, and recover from disruptions (Braynt, 2021; Manyena et al., 2019). As mentioned by Yarveisy et al. (2020), absorptive, adaptive, and restorative capacities are the capacities associated with PAR. In addition to these capacities, Kozine et al. (2018) noted that anticipative, adaptive, absorptive, and restorative capacities achieve PAR. Simultaneously, Rathnayaka et al. (2024) demonstrated that anticipative or planning capacity is necessary for PAR with the other capacities. A thorough probe into the available literature found four main capacities which determine the PAR of an organisation. In other words, the PAR capacity of an organisation is composed of four capacities, which can be named as anticipative capacity, absorptive capacity, restorative capacity, and adaptive capacity. According to Kozine et al. (2018), anticipative capacity refers to the capacity of physical assets to foresee potential disruptions and provide proactive measures to reduce their impacts. Anticipative capacity provides preparedness for future disruptions, including environmental disruptions. As Vugrin and Camphouse (2011) mentioned, absorptive capacity is the extent to which a system can absorb shocks from different disruptions. On the other hand, 20 it refers to the capability or inherent ability of the system to minimise the negative impacts caused by disruptions. Further, absorptive capacity is the degree to which a system can absorb the negative impact of system disturbances and minimise consequences with much effort (Richter, 2015). According to Mottahedi et al. (2021), restorative capacity is the degree to which the system can effectively restore its damaged performance. Similarly, this capacity incorporates the vital ability to restore complete functionality efficiently and effectively based on disruptions (Rahi, 2019; Yang et al., 2023). Finally, adaptive capacity expresses the ability to adapt (Engle, 2011). Adaptive capacity is considered the ability to quickly and effectively adapt to changing conditions and respond to disruptions that could impact its functionality (Comes & Van De Walle, 2014; Kim et al., 2024).

3.3 CAPACITY BUILDING IN PHYSICAL ASSET RESILIENCE

Capacity building is a concept that rose to provide practices, policies, and thoughts for the management of disruptions (Tadele & Manyena, 2009). As mentioned by Brown et al. (2001), capacity building is an ongoing process that is continued through several levels, including individuals, groups, and organisations, to improve their capabilities to identify and achieve improvement obstacles (Brown et al., 2001). Therefore, to perform major activities effectively and to enhance and strengthen over time, capacity building provides the evidence-based process of building abilities of any context (Brown et al., 2001). Specifically, capacity building strengthens an organisation's ability to achieve its objectives by developing effective practices, resources, policies, and skills (Lammert et al., 2015). Through reviewing existing literature, four key elements of capacity building have been identified. They are policies, practices, resources, and skills. Accordingly, capacity building in the context of PAR refers to the systematic process of developing or strengthening the skills, resources, policies, and practices needed to enhance physical assets' ability to anticipate, absorb, adapt to, and recover from disruptions. The following explains how these elements collectively contribute to capacity building in the PAR in an organisation.

3.3.1 Establishing Policies for Capacity Building in PAR

As mentioned by Moteff (2013), policy is a deliberate combination of principles to guide decisions and achieve rational outcomes, serving as a foundation for making consistent decisions and can be applied in various contexts. Simultaneously, in this context, policies underlie the other three elements. i.e., practices, resources, and skills depend upon the organisation's PAR policy. Accordingly, regular maintenance helps prevent asset failures by addressing potential issues before they become major problems (Organisation for Economic Co-operation and Development [OECD], 2021). However, this can be allowed through the maintenance policy, and it ensures that physical assets are regularly maintained to prevent disruptions and improve their ability to withstand disruptions. The maintenance policy incorporates the preventive and predictive maintenance strategies that can significantly improve PAR (Aspell, 2024). Regularly scheduled maintenance tasks based on manufacturer recommendations and organisation standards help maintain physical asset functionality and prevent unexpected failures. On the other hand, utilising data analytics and technology can help to forecast when maintenance should occur, preventing failures before they happen (Aspell, 2024). Another significant aspect of policies is employee training. This policy should be developed to allow employees to be trained in all aspects of the physical assets, including emergency procedures, asset management, and business continuity planning (Tadele & Manyena, 2009). For instance, regular fire drills and emergency preparedness training should be incorporated into the organisation's overall training policy, certifying that employees are familiar with procedures for managing various types of disruptions (Robertson et al., 2015). Thus, this revealed, these policies should outline the frequency of training and the types of scenarios that employees should be prepared. On the other hand, by having physical assets procedures for disruptions management and a clear plan in place, business organisations can minimise downtime and ensure business continuity, which is essential for maintaining resilience (Australian Capital Territory [ACT], 2024). While a disruption management policy is important, effective communication is equally essential for enabling PAR. It facilitates coordination, risk management, and stakeholder engagement throughout the resilience-building process. This revealed the requirement of the communication policy. It not only affects immediate response but also supports long-term restorative efforts. For instance, assessing the effectiveness of communication precautions post-event can inform future improvements and adaptations, ensuring that lessons learned are integrated into ongoing PAR planning. Therefore, a robust communication policy is essential in this context. In addition, worker preparation involves maintaining physical assets effectively, ensuring they can withstand and recover from disruption (Robertson et al., 2015). Therefore, this preparation can be introduced as a policy in PAR. The operator preparation policy is an essential aspect of a commitment to continuous improvement. Organisations must regularly review their resilience strategies, learn from past disruptions, and adapt their approaches based on new insights and emerging disruptions.

3.3.2 Implementing Practices for Capacity Building in PAR

Practice is generally referred to as repeated activity for acquiring or maintaining proficiency in it (Esmalian et al., 2022). It includes the working methods and approaches that improve the efficiency and effectiveness of an organisation (Luenendonk, 2017). According to Bukowski and Werbińska-Wojciechowska (2020), the implementation of maintenance protocols aimed at ensuring the continued functionality, efficiency, and

safety of physical assets throughout their lifecycle and having the proper maintenance recovery approaches can enhance resilience in the physical asset. This highlights that improving the maintainability of physical assets can contribute to it. Continuous monitoring can detect potential disruptions before they increase into severe failures or other interruptions. However, by analysing real-time data, predictive maintenance can be implemented to address disruptions before they cause disruptions. Monitoring physical assets before disruptions and understanding their impacts helps identify vulnerabilities and inform measures for improving resilience (APEC, 2009). Thus, conducting post-event damage assessment as a practice helps to take recovery planning by highlighting areas where physical assets can be restored with enhanced resilience characteristics. On the other hand, post-event damage assessments for physical assets involve rapid and comprehensive evaluations of disruption impacts on infrastructure, buildings, and critical physical assets to inform recovery and disruption impact reduction. These assessments combine hazard modelling, exposure data, structural vulnerability analysis, and advanced technologies to quantify damage and prioritise reconstruction (Johnston et al., 2024). The development and implementation of standard operating procedures (SOPs) for routine operations, maintenance, and emergency response are essential in allowing consistent, efficient, and safe practices (Harwood & Nieto-Gomez, 2017). Consequently, it provides structured processes for maintaining and repairing physical assets, as well as responding to disruptions, including natural disasters, fires, and physical asset failures (Harwood & Nieto-Gomez, 2017). According to Borg et al. (2022), allowing staff to be well-trained in the SOPs and emergency response protocols allows quicker recovery from disruptions. The regular conducting of fire drills and ensuring staff are trained in emergency procedures helps maintain preparedness for all disruptions (Robertson et al., 2015). On the other hand, Tracey et al. (2017) pointed out that business continuity planning allows an organisation can continue to operate their physical assets during and after disruptions. Further, it emphasised, organisations to identify and map their physical assets, which is essential for understanding what resources are available during a disruption. This asset-mapping process helps organisations recognise the strengths they possess. In addition to these practices, physical asset risk assessments help identify vulnerabilities in physical assets, allowing for the mitigation of the impacts of disruptions (Klerk, 2024). Along with conducting risk assessments, it supports continuous development by aligning with goals that focus on building resilience capacity in physical asset investments (Cassottana, 2023). Hence, conducting the physical assets risk assessments is essential for this context. On the other hand, business organisations are concerned about the continuous business process within the organisation (Zhang et al., 2021). Therefore, companies need to require their physical assets to be properly repaired. So that they can optimise the inventory of spare parts. Further, an optimised inventory spare parts system ensures that critical spare parts are readily available, consequently reducing unplanned downtime and associated costs (Ajayat, 2024). Another one is scenario planning for disruptions. As pointed out by Bullis (2024), scenario planning is a strategic practice that enhances resilience by preparing for potential future disruptions. For instance, by developing strategies for various scenarios, organisations can enhance their resilience and adaptability, ensuring they remain operational even during disruptions (Harris, 2024). Further, this can involve exploring a range of potential disruptions in the future. Utilising this practice, organisations can create flexible plans that allow them to respond effectively to unforeseen disruptions (Skemp et al., 2020). Hence, this adaptability is essential for this context.

3.3.3 Enhancing Resources for Capacity Building in PAR

Resources refer to anything that can be available within a community, society, or organisation that can be utilised to achieve specific goals related to a particular field (Dharmadasa et al., 2023). One key resource in building PAR is having a backup physical asset that can maintain the operation even in disruptive conditions (Alberti, 1999; Kusumastuti et al., 2014; Pant et al., 2014). Consequently, by having physical backups, business organisations can minimise downtime and the impact of unexpected disruptions. This helps in safeguarding against potential financial losses associated with physical asset breakdowns (Crudu, 2024). Simultaneously, this is essential for maintaining service delivery and customer trust (Todd, 2024). Warehouses and evacuation centres are also important resources. Warehouses serve as storage facilities for major spare parts and backup physical assets, ensuring that essential resources are readily available when needed (Ciriaco & Wong, 2022). On the other hand, during disruptions, evacuation centres provide safeguarding personnel and shelter, and supplies. Similarly, supportive equipment and vehicles are also significant for physical asset resilience. Reliable, supportive equipment and vehicles for maintaining service delivery, as they support operations and confirm the smooth functioning of major physical assets. For instance, vehicles provide mobility during disruptions, allowing organisations to move resources efficiently. Another one is that the incorporation of new technology can allow more advanced users to access physical assets. Physical asset monitoring systems, which include IoT devices and sensors, provide real-time data on the condition and performance of physical assets. For instance, IoT sensors play a key role in real-time physical asset condition monitoring, predictive maintenance, and the reduction of risk from unexpected failures. On the other hand, simulation and modelling Platforms, including a physical assets risk model network, allow for wide effects of disaster-induced failures and post-disaster restoration. Renger et al. (2002) noted that Geographic Information Systems (GIS) provide visualisation of disruption impacts and resilience challenges, and support to scenario analysis and strategic planning for disaster preparedness and recovery. In addition, adequate financial resources increase physical asset performance against disruptions. Besides, many business organisations face a backlog of deferred maintenance, which can increase vulnerabilities to disruptions. However, investing in resilience is critical to prevent minor issues from escalating into significant problems that compromise physical asset integrity. This retrieval, developing comprehensive capital plans that prioritise resilience, can be more cost-effective than reactive measures post-disaster. It is important to separate them into specific categories. Firstly, capital investments refer to long-term financial allocations aimed at upgrading or acquiring physical assets with enhanced resilience features, such as climate-proof physical assets or sensor-based monitoring systems (Corti et al., 2022). Secondly, operational budgets support routine maintenance activities and daily operational needs that contribute to resilience through consistent performance and early problem detection (Karamouz & Hojjat-Ansari, 2020). Thirdly, contingency funds are significant for answering sudden disruptions, allowing for rapid repairs or temporary replacements to maintain continuity. In addition, pre-arranged financial mechanisms, including insurance, reserve funds, or pre-approved emergency financing, allow organisations to act swiftly when early warning systems indicate a potential disruption (Azadegan et al., 2021). Moreover, reliable physical assets are a crucial resource for enhancing PAR (OECD, 2024). Along with this, reliable physical assets allow operations to continue smoothly, even in the face of disruptions such as natural disasters or mechanical breakdowns. On the other hand, this

resource is important for maintaining stakeholder trust during turbulent situations (Beemboster, 2023). Another significant resource is a skilled workforce. According to Sam (2021), a skilled workforce ensures timely inspection, maintenance, and repair activities, which are critical for managing physical asset life and mitigating risks. The training and development of this workforce are significant for building capacity in PAR (Madrigano et al., 2017). The workers need to be regularly trained on the latest practices within their work and new technologies, and emergency procedures (Madrigano et al., 2017). On the other hand, leadership and governance structures affect fostering a skilled workforce by setting clear policies, providing ongoing support, and aligning human resources with the organisation's strategic goals in asset management (Helmrich & Chester, 2022). Consequently, they ensure that the workforce is adequately prepared for both routine operations and emergency response (Helmrich & Chester, 2022). In addition to internal resources, external resources are involved in this context. One such major external resource is having a proper supply chain, which ensures the continuity of material, equipment, and service flows required for physical asset resileince (Trucco et al., 2018). Additionally, the stakeholder network includes partnerships with local authorities, emergency responders, service contractors, community groups, and professional bodies that provide valuable resources such as technical expertise, regulatory support, and emergency coordination (Li & Ji, 2021). This revealed, these networks strengthen PAR by facilitating information sharing, mutual aid, and coordinated responses.

3.3.4 Enhancing Skills for Capacity Building in PAR

According to Perera et al. (2017), skills are the abilities that individuals or groups possess. Further emphasised that they significantly contributed to overcoming the desired outcomes effectively. Skills refer to the abilities and expertise that people can build through knowledge, training, and experience. Particularity in the context of PAR requires a combination of technical skills that can support human behaviour and physical assets (Thomas et al., 2019). For instance, having familiarity with specific tools and technologies that support resilience, such as simulation software and monitoring systems, is important (Woods, 2015). Thus, these skills can help in modelling scenarios and evaluating the resilience of physical assets. Similarly, as a technical skill, utilising Internet of Things (IoT) sensors allows continuous monitoring of physical asset conditions (Klerk, 2024). Therefore, these skills allow for proactive maintenance and rapid response to potential disruptions, significantly enhancing PAR during disruptions. On the other hand, community engagement skills require engaging with local parties to understand their needs and involve them in planning and decision-making processes. These include skills in public outreach, education, and participatory

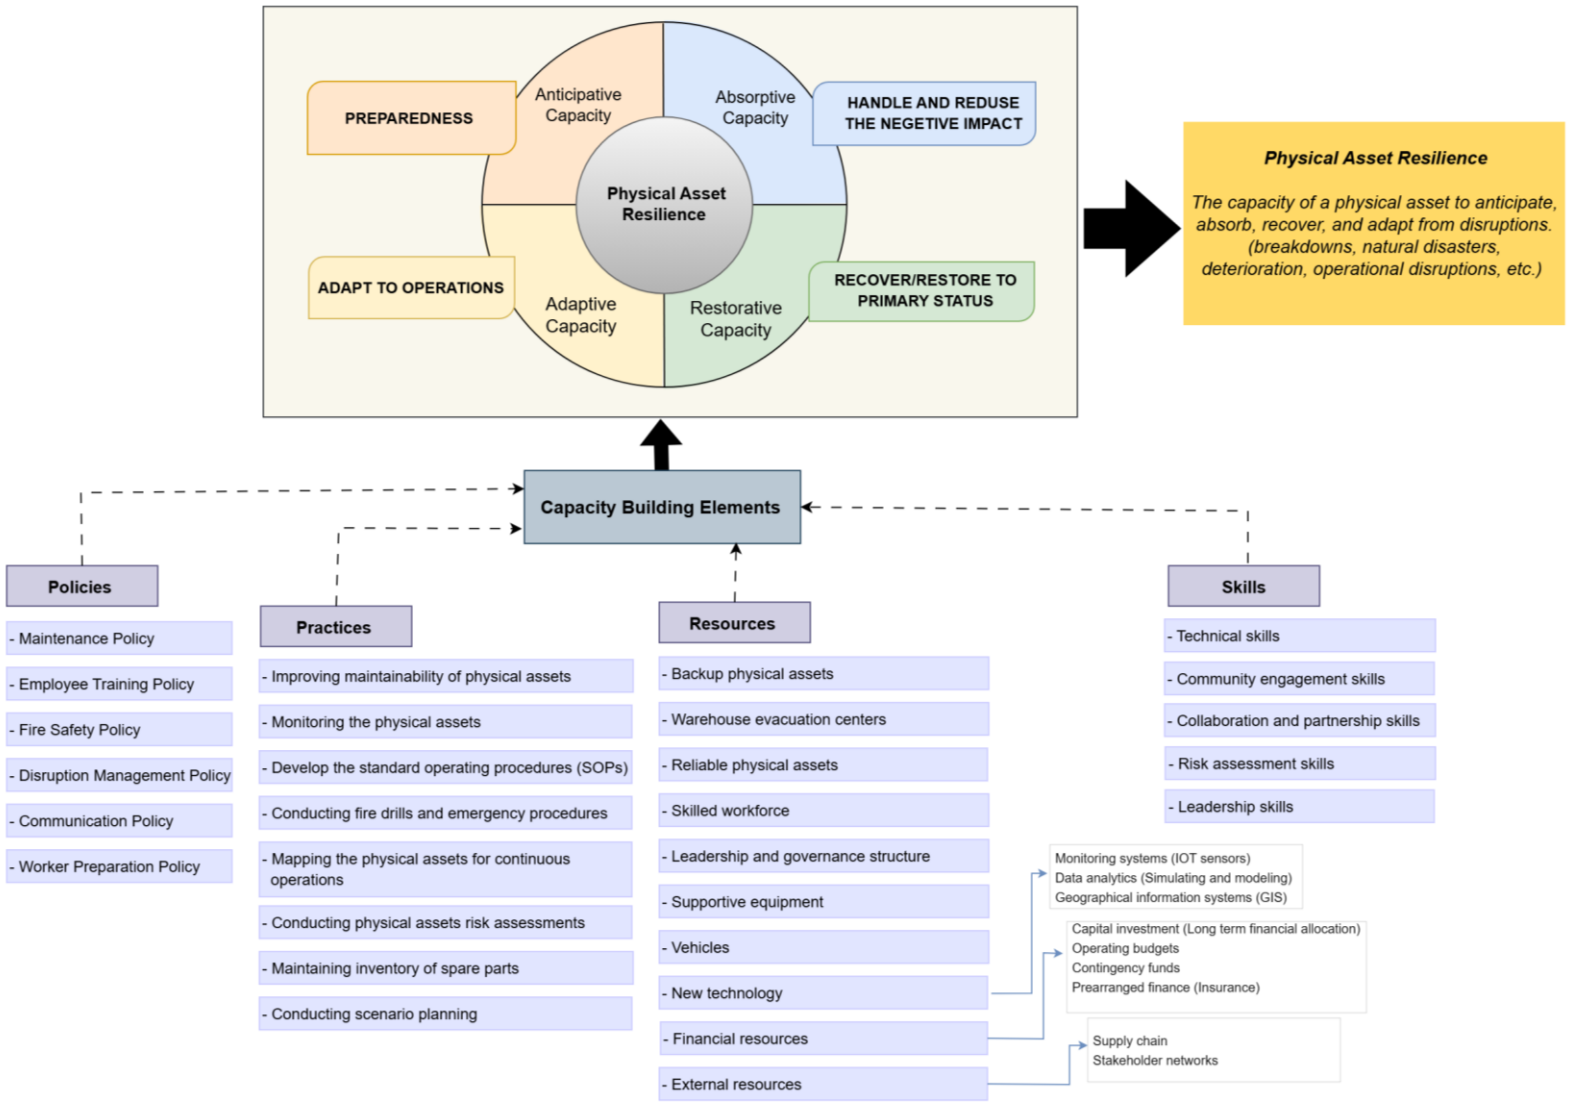

Figure 1: Conceptual Framework for Capacity Building in PAR

planning stages (Danaher et al., 2014). Moreover, community engagement should assist combined efforts among various stakeholders (Johnston et al., 2024). Thus, collaboration helps develop effective emergency plans. Strong community engagement and partnership skills are essential, as coordination among stakeholders, such as the government and private sector, enables knowledge sharing (Wieszczeczynska et al., 2024). Another one is understanding and addressing vulnerabilities, which is a contribution to developing resilience strategies. This involves skills in data collection, analysis, and interpretation to identify vulnerabilities and identify measures (Fleming & Ledogar, 2008). This emphasises that risk assessment skills are essential for capacity building in PAR. Moreover, having properly structured leadership skills is significant for coordinating disruption response efforts and managing resources efficiently (Danaher et al., 2014). In addition, leaders or top managers need to adjust strategies and operations in response to changing circumstances. This adoption is crucial in environments characterised by volatility, uncertainty, and ambiguity (Zamani & Ait Soudane, 2022).

4. CONCEPTUAL FRAMEWORK FOR CAPACITY BUILDING IN PAR

The conceptual framework developed in this study (Figure 1) integrates four key PAR capacities with essential capacity-building elements: policies, practices, resources, and skills. It serves as a guide to understanding how this works together to strengthen PAR in organisations. Anticipative capacity involves preparedness and the ability to foresee disruptions. Absorptive capacity refers to minimising the impact of disruptions, while restorative capacity focuses on the quick recovery of physical asset functionality. Adaptive capacity allows long-term improvement by adjusting operations. Capacity-building elements support these capacities through policies (e.g., maintenance, disruption, and fire safety), practices (such as risk assessments and monitoring), resources (financial, technological, and network-based), and skills (technical and community engagement). Together, these aspects contribute holistically to building resilience in physical assets. The legend of the conceptual framework (Figure 01) is as follows,

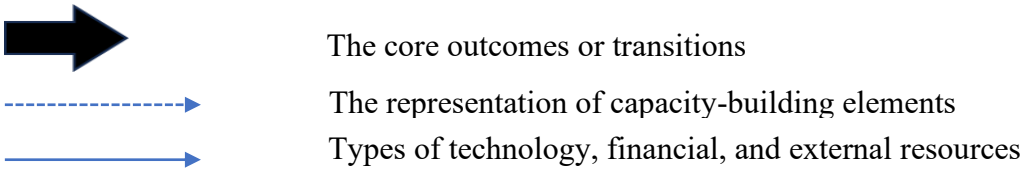

Figure 2: Guide to the conceptual framework

5. CONCLUSION

This study emphasises that the capacity building (PAR) in business organisations strongly depends on four key capacity-building elements. This review of literature aimed to identify the key capacity-building elements that contribute to strengthening PAR in business organisations. By reviewing existing studies, it was established that PAR is characterised by four capacities: anticipative, absorptive, restorative, and adaptive. The review further emphasised that policies, practices, resources, and skills are significant elements of capacity building, each allowing a critical place in improving PAR within business organisations. The findings identified six policies, eight practices, ten resources, and five skills that collectively allow physical assets to anticipate potential disruptions,

absorb their impact, recover or restore efficiently, and adapt to operations Thus, this study fills a gap in the existing literature by proposing a conceptual framework that includes the key elements of capacity building with the four capacities of PAR. However, in this study, it was not examined separately for each PAR capacity. Instead, a general approach to capacity building was considered to support the overall PAR. The need for capacity building in PAR is particularly critical for the apparel manufacturing sector. Which is one of the key economic contributors in Sri Lanka, and these organisations are highly reliant on their physical assets when driving their business, hence capacity building in this sector becomes an essential need. The conceptual framework developed through this study is intended to be explored further in apparel manufacturing organisations in Sri Lanka, and a more detailed analysis of how capacity building in individual PAR capacities will be conducted.

A HUMAN CENTRED APPROACH TO POST DISASTER RESETTLEMENT HOUSING: CASE SUDY ON WALK-UP APARTMENTS IN SRI LANKA

M.S.N. de Zoysa[1], S.B.A. Coorey[2], M. Thayaparan[3] and L. de Silva[4]

ABSTRACT

The rapid increase of post-disaster involuntary resettlement presents a significant global challenge. Integral to the disaster management cycle, post-disaster reconstruction is pivotal, serving as the backbone of the entire resettlement process. As post-disaster resettlement is a far more sensitive process than providing shelters, it should address the multidimensional requirements of the resettling community as well as the host community from different perspectives. Despite its criticality, existing research indicate, still there is a distrust about the community satisfaction of post-disaster involuntary resettlement in long-term. In Sri Lanka, recent decades have seen floods, landslides, and tsunamis trigger significant resettlements, highlighting a research void concerning the design aspects of these relocations, which critically influence long-term community contentment. Hence, the study focuses on the identification of design related issues of involuntary resettlements with special reference to post-disaster involuntary resettlement walk-up apartments in Sri Lanka which have an essential and futuristic requirement in the resettlement process. Qualitative approach was used for filling the knowledge gaps about the phenomenon, and development of a descriptive knowledge framework of the phenomenon. Accordingly, this study reinforced by a comprehensive literature review and interviews with beneficiaries to validate the findings of the literature. The beneficiary interviews were conducted by selecting two case studies representing two different types of disasters. The anticipated outcome is the formulation of design indicators to guide policymakers and practitioners towards enhancing the efficacy and community satisfaction in future post-disaster housing projects over the long term.

1. INTRODUCTION

The increasing frequency and intensity of natural disasters globally have led to an escalation in disaster-induced population displacements. In Sri Lanka, floods, landslides, and the 2004 tsunami have significantly contributed to internal displacement and necessitated state-led post-disaster resettlement programmes (UN-ISDR, 2009; Correa et. al., 2011).

Disasters have devastating impacts on communities, infrastructure, and the environment. The interpretation of the term 'disaster' varies among different authors and institutions.

The United Nations Office for Disaster Risk Reduction (UNDRR) defines a disaster as a serious disruption of the functioning of a community or a society involving widespread human, material, economic, or environmental losses and impacts, which exceeds the ability of the affected community or society to cope using its own resources. The Federal Emergency Management Agency (FEMA) (United States) defines a disaster as a sudden event causing significant damage, destruction, and disruption to normal life, resulting in a need for external assistance. Moreover, the International Federation of Red Cross and Red Crescent Societies (IFRC) defines a disaster as an event that causes harm to people, property, and livelihoods, disrupts the normal functioning of a community or society, and results in a need for external assistance. Haigh and Amaratunga (2012) viewed disasters as a social phenomenon that occurs when a community suffers exceptional, non-routine levels of disruption and loss.

As Haigh and Amaratunga (2012) stated, disasters caused considerable damage around the world every year, and the need to respond, recover, rebuild or reinstate the built environment affected by disaster can be identified as a major challenge for the countries affected by disasters. Consequently, the post-disaster resettlement is a crucial aspect of disaster response and recovery. It involves the process of relocating affected individuals, families, or communities from their original homes/locations to safer or more suitable locations after a disaster (Silva & Ballinger, 2021; Iuchi & Mutter, 2020; Tiwari et al., 2023). This process is complex and requires careful planning and design to ensure the long-term sustainability of the new settlements. In this context, architectural design approaches play a vital role in ensuring the sustainability of post-disaster involuntary resettlements.

In the context of post-disaster resettlement housing, various design approaches can be observed globally. Accordingly, one of the key design approaches in post-disaster involuntary resettlements is the use of low-rise, high-density housing typologies. This approach has been widely used in several post-disaster resettlement projects worldwide. This approach allows for the efficient use of land and resources while providing adequate living space for the affected communities. However, the use of low-rise, high-density housing typologies also have several drawbacks in the areas of physical and functional aspects (Pellinan, 2012; Davidson et al., 2007), infrastructure and services (Ozumba et al., 2024), social integration and livelihoods (Archer & Boonyabancha, 2011; Mohit & Raja, 2014; Iuchi & Mutter, 2020), cultural appropriateness and psychological anchoring (Iuchi & Mutter, 2020; Haigh & Amaratunga, 2012) reflecting an alignment between housing provision and the physical, social, cultural, and psychological needs of residents (Lizarralde et al., 2010; Asian Development Bank Report, 2014; Bakar & Osman, 2022; Haigh & Amaratunga, 2012; Ahmed, 2010; Pellinen, 2012). Therefore, it is crucial to incorporate appropriate design strategies to address these challenges and ensure the long-

term sustainability of the resettlement projects. As such this research aims to identify the design related issues in post-disaster involuntary resettlement walk-up apartments in Sri Lanka.

2. LITERATURE REVIEW

2.1 POST-DISASTER RESETTLEMENT HOUSING

Maslow's Hierarchy of Needs is a psychological theory proposed by Abraham Maslow in 1943, in his paper "A Theory of Human Motivation." It suggests that humans have a hierarchy of needs that must be fulfilled in a specific order, starting from the most basic physiological needs and progressing to higher levels of psychological and self-fulfilment needs. The hierarchy is often depicted as a pyramid with five levels, arranged from the bottom to the top.

Accordingly, 'housing' is a basic human need that Maslow explained in the hierarchy of needs as a first important level of need similar to food and drink; therefore, it is at the centre of wellbeing; People must have food to eat, water to drink and a place to call home before they can think about anything else. Furthermore, Maslow's theory also demonstrates how important adequate housing is for security and positive development, and this is the second level of need; people must possess the security of a home and family in order to achieve the higher stage of need "self-actualisation" (Bakar & Osman, 2021).

According to Maslow's theory, individuals progress through these levels sequentially, with higher needs becoming dominant only after lower needs are satisfied. However, it is essential to note that not everyone follows this hierarchy in the same way, where individual experiences and cultural differences can influence how people prioritize and pursue their needs. Additionally, Maslow later proposed a sixth level called "Self-Transcendence," acknowledging that some individuals may prioritize helping others or spiritual growth beyond self-actualization.

In this theoretical sense, shelter is one of the key needs that we need to satisfy in a post-disaster context. The classification of shelters can vary based on different perspectives. In a study by Iuchi & Mutter (2020), post-disaster housing arrangements were categorized into four subsequent stages. These stages were based on the accommodation's purpose, the intended duration of stay for disaster-affected individuals, and whether they would resume their regular household activities in that location. Additionally, provided an explanation of how soon these housing provisions need to be provided.

The categories are 1) Emergency sheltering: Quarters for short periods, for hours or overnight, and to be provided within hours; 2) Temporary sheltering: People's temporary displacement into other quarters, within an expected short stay, and to be provided within a day or two; 3) Temporary housing: Resuming household responsibilities and activities in new quarters, arrangements that exceeded a mere emergency or temporary basis, and extend for months, if not years, to be provided within weeks preferably; and 4) Permanent housing: Returning either to their repaired or rebuilt original homes or moving into new permanent quarters, to be provided within few years.

Irrespective of the type of shelter provided, every shelter has fundamental needs that encompass the key requisites shown in Figure 1. Security and protection from weather can be the priority for those who are relocating to such shelters immediately aftermath of a disaster. However, the priorities of the people change over time when they tend to stay

in such shelters for a longer period. Hence, post-disaster resettlement projects should consider all the key requisites of a shelter into account, not just the immediate priorities of the affected communities.

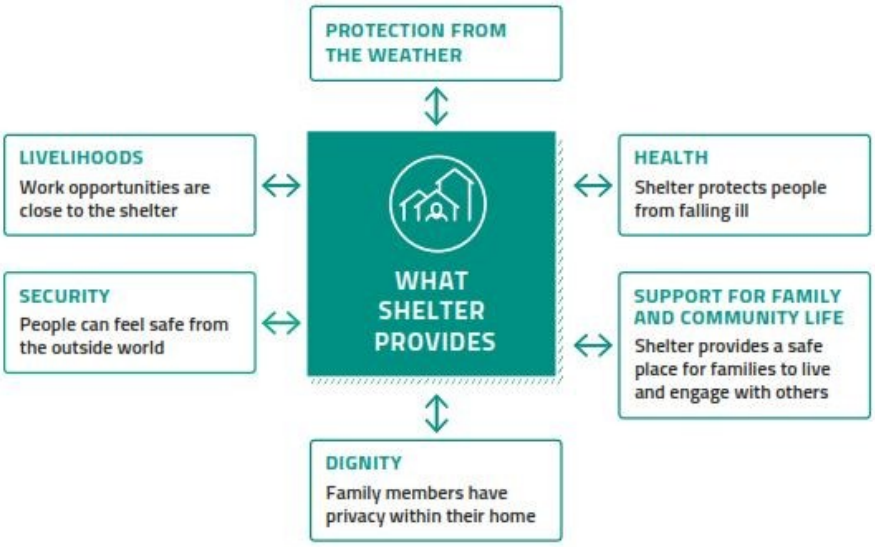

Figure 1: What shelter provides

The impacts of disasters on the built environment sector and vice versa have been widely discussed in the literature by various scholars in the field (Haigh & Amaratunga, 2012; Paul et al., 2023; Ozumba et al., 2024). As highlighted in the National Involuntary Resettlement Policy (NIRP), the resettlement process should restore the affected community's living standards and integrate them into their new settlements (Godamunne, 2013). Also, it should ensure that the affected people are not negatively impacted. Further, it describes that those people who are living in vertically developed resettlements, have key issues in landlessness, joblessness, homelessness, marginalization, food insecurity, loss of access to common property resources, increased morbidity, mortality, and community disarticulation (Godamunne, 2013).

When considering the current design approaches, single-story individual houses are the most commonly available and community acceptable typology in the involuntary resettlements. However, with the issues of the availability of limited safer lands and other related issues, single-story individual housing is the most critical typology in the present context. Further, as Atmowardoyo (2018) stated, the use of valuable, productive agricultural lands for the reconstruction of new settlements is also a critical factor. Because the economic loss and the degradation of agricultural land could cause some serious problems in the future which could not be exactly estimated from now. Accordingly, the study was mainly focused on the post-disaster involuntary resettlement walk-up apartment housing, which has a futuristic requirement. The following section discusses the issues identified in the post-disaster resettlement housing.

2.2 DESIGN RELATED ISSUES IDENTIFIED IN THE POST-DISASTER RESETTLEMENT HOUSING

The community satisfaction in post-disaster permanent housing provision is determined by various indicators, including physical, social, and economic factors (Pellinan, 2012; Shrestha et al., 2025; Asnudin et al., 2024; Dharmadasa et al., 2024; Xiang et al., 2024; Capell & Ahmed, 2021). The physical indicators relate to the quality of housing infrastructure and amenities, such as the availability of clean water, sanitation facilities, and electricity. Adequate space, ventilation, and lighting are critical factors that contribute to the physical well-being of residents (Shrestha et al., 2023; Montalbano & Santi, 2023; Dias et al., 2016; Mohit, 2014). In addition, accessibility to healthcare facilities, schools, and transportation systems is an important consideration in determining community satisfaction. Social indicators relate to the social fabric of the community, including the quality of relationships among neighbours and with outside agencies, the sense of safety and security, and the degree of social cohesion (Dharmadasa et al., 2024; Hassan et al., 2023; National Academies of Sciences, Engineering, and Medicine, 2015; Mohit, 2014). Community engagement and participation in decision-making processes are important social indicators that contribute to community satisfaction. Economic indicators are critical in determining community satisfaction, including the availability of employment opportunities, access to credit and financial services, and access to markets for the sale of goods and services. The affordability of housing and the cost of living are important economic considerations that contribute to community satisfaction (Islam et al., 2025; World Bank, 2025; Tiwari et al., 2023; Haigh & Amaratunga, 2012).

Based on the information gathered through the literature review, it has been identified that the multifaceted challenges of post-disaster housing resettlement, both globally and Sri Lanka, can be comprehensively analysed through a structured framework comprising three critical phases: planning, implementation, and evaluation. This categorization not only provides analytical clarity but also aligns with contemporary disaster risk reduction frameworks and best practices for resilient and sustainable housing recovery (Davidson et al., 2007). Though the following analysis is presented in three phases, the design related issues are mainly to be addressed during the planning stage as any design-related errors will create impacts during the implementation and evaluation phases.

The planning phase serves as the conceptual foundation for resettlement initiatives. However, this phase is often characterized by significant gaps in site selection, community engagement, and context-sensitive design. Resettlement sites are frequently chosen based on land availability or administrative convenience rather than robust hazard assessments, participatory consultations, or social impact evaluations (Boano & García, 2011; Davidson et al., 2007). As a result, communities are frequently relocated to peripheral or environmentally vulnerable areas, as documented in post-tsunami India and post-earthquake Iran (Bakar & Osman, 2022). Sri Lanka has not been immune to similar challenges, with resettlement sites often developed on marginal lands lacking essential infrastructure and services (Senanayake et al., 2022).

Furthermore, the absence of genuine community participation in the planning process undermines both the suitability and acceptance of housing solutions. Standardized designs; typically produced by external consultants or donor agencies; tend to neglect cultural norms, spatial traditions, and household structures (Dayaratne & Kellett, 2008;

Pellinan, 2012). The exclusion of culturally significant features such as verandahs, internal courtyards, and semi-outdoor kitchens can disrupt daily routines and diminish the adaptability of living spaces (Pellinan, 2012). Compounding this issue is the dominance of technocratic, risk-centric planning paradigms, which prioritize structural resilience while neglecting broader recovery dimensions such as emotional well-being, cultural continuity, and livelihood proximity (Iuchi & Mutter, 2020). This misalignment with community values often leads to dissatisfaction, informal alterations, or even abandonment of provided housing (Pellinan, 2012; Davidson et al., 2007).

The implementation phase, which operationalizes the resettlement plan into physical environments and services, reveals additional deficiencies. Uniform housing templates are commonly deployed with little regard for household diversity or evolving needs. In Sri Lanka, walk-up apartment resettlements have drawn criticism for rigid layouts, poor ventilation, and limited communal space, which collectively restrict residents' capacity for spatial personalization (Pellinan, 2012). Comparable issues have been observed internationally; in Iran, Indonesia, and Haiti; where inflexible housing solutions ignored vernacular knowledge and environmental responsiveness (Bakar & Osman, 2022; Ozumba et al., 2024).

The evaluation phase, which should function as a mechanism for accountability and continuous improvement, is arguably the most underdeveloped. Post-disaster housing programmes tend to focus on quantitative metrics such as unit completion and financial expenditure, while qualitative indicators like user satisfaction, cultural relevance, and psychosocial recovery remain underexplored (Ahmed & McEvoy, 2010; Xiang et al., 2024). This narrow evaluative lens curtails the ability of institutions to adapt practices based on lived experience. In Sri Lanka, evaluations such as those by researchers like Senanayake et al. (2022) have exposed persistent dissatisfaction, particularly in high-density apartment schemes. Common issues include overcrowding, poor ventilation, lack of privacy, and geographic dislocation from employment and services.

Equally problematic is the limited application of evaluation outcomes in future planning and design. Institutional learning is often minimal, and many of the same planning and implementation flaws are repeated across different projects (Davidson et al., 2007; Iuchi & Mutter, 2020). Moreover, most evaluations lack participatory methodologies, excluding the perspectives of the very communities they are intended to serve (Haigh & Amaratunga, 2012). Without integrating community voices, such assessments fail to capture the complex social and cultural dynamics that influence housing success.

In summary, the analysis underscores the multifaceted impact of disaster-induced involuntary resettlement housing emphasizing the need for design professionals to consider the broader implications of their design decisions on community building, resident satisfaction, and the integration of functional spaces. Accordingly, the data highlights a compelling argument for a more resident-centred approach in housing development, one that prioritizes the creation of spaces that support community engagement, personalization, and overall quality of life. Finally, involuntary resettlement can be identified as a transformation of a specific environment in social, cultural, environmental, and economic terms. Hence, the entire resettlement should be a sustainable solution for society.

3. RESEARCH METHODOLOGY

This study adopts a qualitative approach to examine design-related issues surrounding disaster-induced involuntary resettlement housing in both global and local contexts. A comprehensive literature review was conducted to establish a theoretical and contextual foundation, drawing on existing research to identify key design related issues in the disaster-induced involuntary resettlement housing. These findings were validated and contextualized for the involuntary resettlement housing in Sri Lanka. A case study research strategy was adopted for this purpose. A case study is a comprehensive analysis of an individual, a group within an organisation, or a specific event that has distinctive properties (Atmowardoyo, 2018). A multiple holistic case study was conducted to identify the design related issues in post-disaster resettlement housing. 'Post-disaster resettlement housing' was identified as the case study boundary and 'design-related issues' was selected as the unit of analysis. As such, two case studies focused on post-disaster involuntary walk-up apartment resettlement housing projects representing two different types of disasters (landslide and tsunami) in Sri Lanka were selected.

The first case study examined a tsunami-induced resettlement housing project with 100 two-roomed housing units. This case represents coastal displacement and the corresponding resettlement strategies adopted in such contexts. The second case study explored a housing project initiated due to landslide displacement with 75 two-roomed housing units, thereby reflecting a contrasting geographical and environmental context, namely, inland displacement due to terrain instability. In both cases, the occupants have been living in these facilities for almost 10 years, which was intentionally considered to ensure that the satisfaction level of the occupants to be more realistic. Each case study involved the collection of data through semi-structured interviews with twenty (20) beneficiaries from each resettlement project. Accordingly, 40 interviews with respondents from different households in the resettlement apartment, which consisted of houses from different floor levels, were conducted. The interviews were arranged face-to-face with the intention of the researcher to visit these facilities in person to observe the design-related issues persistent in those housing projects. The selection of these two cases enables the study to analyse variations in resettlement outcomes, planning approaches, and community responses across different disaster types. Both cases serve to validate the key design relate issues identified in the literature while contributing practical insights for future resettlement planning and policy development.

4. ANALYSIS AND FINDINGS OF CASE STUDIES

The case studies aim to provide grounded insights into the lived experiences of affected communities and to assess the effectiveness of current resettlement housing in terms of architectural design features. The occupation of the community from Case study 1 consisted of private sector workers and fishermen, whereas Case study 2 consisted of private sector workers and self-employed workers.

Table 1 presented the interview findings in a structured manner based on the cross-case analysis.

Table 1: Contextualised design related issues in case studies

Design related issues	Case study 1	Case study 2
Design deficiencies	Satisfied with internal layout, except the size, building orientation and parking facilities. Inadequate space for home gardening.	Satisfied with internal layout. Inadequate space for recreational facilities, parking facilities and home gardening.
Administrative convenience of site selection for housing	Transportation is not a concern.	Need for safe and accessible transportation infrastructure.
Quality of construction	Not satisfied.	Satisfied.
Quality and accessibility of infrastructure and amenities	Need for enhanced utility services, concerns with the adequacy of water supply, electricity, and waste management systems.	Need for enhanced utility services, concerns with the adequacy of water supply, electricity, and waste management systems. The community desires for internet connectivity.
Economic actives	Inadequate space for income-generating activities.	Inadequate space for income-generating activities.
Absence of genuine community participation in the planning and decision-making process	Lack of community involvement in the planning and construction process.	Lack of community involvement in the planning and construction process.
Exclusion of culturally significant features and misalignment with community values	Satisfied with culturally significant features.	Culturally significant features like worship areas are not included.
Little regard for household diversity or evolving needs	No provision for future extensions.	No provision for future extensions.
Social cohesion due to limited communal space	Comparatively satisfied with the communal space provided in the building design.	Limited communal space to associate with neighbours or recreational activities.
Poor ventilation	Not a concern.	Compared to case study 1, the ventilation is considered poor.
Safety and Security	Dissatisfaction with privacy, safety and security issues.	Dissatisfaction with privacy, safety and security issues.
Sustainability features	Strong interest in incorporating sustainable features such as solar panels.	Strong interest in incorporating sustainable features such as solar panels. Demonstrated collective awareness of renewable energy sources and their benefits.

As per Table 1, the key design-related issues identified in the literature were contextualised and validated through real-life case studies. There has been similarities and differences between the case studies with respect to the identified design related features. Accordingly, Case Study 1 community is comparatively more satisfied with the communal space and culturally significant features provided in the buildings, along with the transportation infrastructure. This was mainly due to the selection of building sites of case study 1 which was at a sub-urban area where the accessibility and spacing were comparatively better than the Case Study 2 which are located in rural areas. However, the level of satisfaction with quality of construction was comparatively low in Case Study 1. Further case study 2, the community emphasized the importance of reliable internet access in today's digital world.

There have been more similarities than differences between the two cases, as observed in Table 1. The issues related to quality and accessibility of infrastructure and amenities, inadequate space for income-generating activities, lack of community involvement in the planning and construction process, lack of provision for evolving needs and safety and security were the key concerns in both case studies. Additionally, the respondents from both cases expressed their strong willingness and support towards sustainable features.

These findings suggest that while certain infrastructural needs are universally relevant across resettlement contexts, and specific concerns influenced by the geographic setting, and socio-cultural dynamics which require site specific responses. Addressing both the shared and unique concerns identified in each case study will be essential for the development of future resettlement projects that are not only functional and safe but also resilient, inclusive, and aligned with the evolving needs of affected communities. Proposing solutions for the design related issues will be the way forward of this ongoing research study.

5. CONCLUSIONS

Housing must not only provide shelter but also support community building, facilitate personalization, and enhance the overall quality of life for residents. Accordingly, a resident-centred approach is essential, which can actively foster social engagement and long-term satisfaction. Further, the involuntary resettlement represents a profound transformation across social, cultural, environmental, and economic dimensions. As such, resettlement efforts must aim to deliver sustainable and holistic solutions that extend beyond physical infrastructure to include cultural continuity and social cohesion.

The study reveals both similarities and differences in terms of design related issues across different resettlement contexts representing different types of disaster, geographical conditions, and socio-cultural backgrounds of the occupants. Accordingly, the issues related to quality and accessibility of infrastructure and amenities, inadequate space for income-generating activities and evolving needs, lack of community involvement in the planning and construction process, and safety and security related issues were highlighted as the key concerns in both case studies. Additionally, certain design related issues were highlighted more by one case study than the other indicating the context-specific findings. Accordingly, the findings emphasize the importance of tailoring resettlement strategies to address both common needs and context-specific concerns. This dual approach is critical for developing resettlement projects that are not only functional and secure but also resilient, inclusive, and adaptive to the evolving needs of displaced communities.

Although recent efforts have increasingly focused on structural resilience, there remains a lack of theoretical and practical frameworks to assist design professionals in creating built environments that address the psychological, cultural, and symbolic dimensions of space which factors that are essential for meaningful recovery and identity reconstruction. Accordingly, this research intended to address this gap by analysing the satisfaction level of the communities that occupied post-disaster resettlement housing.

In providing solutions to the identified design related issues, this research intends to conduct interviews with design professionals in Sri Lanka using qualitative survey strategy as the way forward of this study. Sri Lanka is prone to disasters such as flood, landslide and tsunami. The data collected mainly reflect two types of disasters such as landslide and tsunami. However, as both the landslide and flood are similar in terms of the frequency and intensity of disaster risk in Sri Lanka, the findings obtained can be generalisable within the Sri Lankan context.

A REVIEW OF PROCUREMENT AND MANAGEMENT OF BUILDING SERVICES SYSTEMS: COMPLEXITIES AND TECHNOLOGY ADOPTION

Sachindra Hewavitharana[1], Srinath Perera[2], Xiaohua Jin[3], Krisanthi Seneviratne[4] and Keivan Bamdad[5]

ABSTRACT

Rapid advancements in digitalisation are reshaping the global supply chains and revolutionising traditional procurement and management practices. Within the construction industry, the procurement and management of building services systems present greater complexities compared to other construction elements. This study aims to identify these complexities and explore the potential of emerging technologies to address them. A scoping literature review of 32 peer-reviewed articles was conducted to identify the complexities in the procurement and management of building services systems from different perspectives and to identify applicable digital technologies. The findings reveal that complexities span across collaboration, approvals, design requirements, technical calculations, life cycle, communication, regulatory requirements, maintenance, cost, technical skills, etc. Technologies such as Building Information Modelling (BIM), Blockchain, Data Analytics and Artificial Intelligence (AI), Digital Twin and IoT, and Building Management Systems have been widely adopted to address these complexities. This identification urges the necessity of a systematic and technology-integrated approach to the procurement and management of building services systems. The findings from this research assist construction professionals in selecting appropriate technologies aligned with the specific requirements and phases of building services procurement and management.

1. INTRODUCTION

Building Services Systems (BSS), including heating, ventilation, and air conditioning (HVAC), electrical, plumbing, fire services, and vertical transportation, play a critical role in making buildings comfortable, functional, and safe for end-users. They often contribute significantly to both the duration (up to 50%) and cost (up to 50%-60%) of construction projects, depending on project size and complexity (Chauhan et al., 2022). The installation of BSS frequently lies on the critical path of construction schedules, directly influencing project timelines and outcomes (Shoesmith, 2010). Unlike conventional building components, such as structural and non-structural components, BSS are highly specialised, requiring expert knowledge for installation, long-term lifecycle management, multidisciplinary coordination, and compliance with strict performance standards (Akhil & Das, 2019; Wan & Kumaraswamy, 2012; Wu et al., 2022). These inherent complexities are further intensified by fragmented supply chains, changing client requirements, compliance with regulatory guidelines, and frequent design changes during the initial phases of construction projects (Khan et al., 2023). Because of this nature, procurement and management (P&M) of BSS are challenging, remain inefficient and prone to errors (Hewavitharana et al., 2024). Here, procurement and management refer to operations throughout the lifecycle of BSS.

Consequently, with the advent of industry 4.0, construction companies have explored ways of utilising technologies such as Building Information Modelling (BIM), Blockchain, Internet of Things (IoT) and Building Management Systems (BMS) in the P&M of BSS (Francis & Zhou, 2025; Husin & Kristiyanto, 2024; Perera et al., 2024). The adoption of these technologies in building services systems is still emerging with varying degrees of success and acceptance. Hence, it is vital to identify the promising research directions in this domain.

This study aims to identify the complexities of P&M of BSS and drivers and limitations of adopting trending technologies in P&M of BSS. The rest of the paper is organised in the following order: The methodology adopted for the study is presented in Section 2. Section 3 presents the findings and discussion section. Lastly, the conclusion, along with the practical implications of the research and recommendations for further investigation, is presented in Section 4.

2. METHODOLOGY

In this study, a scoping review was carried out instead of a systematic review. The reason for selecting a scoping review was to focus on the breadth of the literature in this area, as it had not been explored extensively in the past. Accordingly, three research questions were formulated to guide the scoping review.

1. Why is the P&M of BSS complex than the P&M of other construction elements?
2. What are the trending technologies in P&M of BSS?
3. How can the identified technologies reduce the complexities in P&M of BSS?

Scopus and Web of Science databases were used to identify relevant documents during the scoping review due to their reputation as the most appropriate and reliable sources for literature reviews. The search string; *("Procure*" OR "Tender*") AND (“Construction” OR “Built Environment” OR “Building services” OR "MEP" OR "Mechanical" OR "Electrical" OR " Plumbing" OR “Structure*” OR “Architecture*” OR “Civil*

Engineering" OR "Construction Engineering" OR "Construction Industry" OR "Construction Management" OR "Construction Engineering and Management") AND (complex OR challeng* OR difficult* OR "high uncertainty" OR inefficien*) AND ("Digital Technologies" OR "Blockchain" OR "BIM" OR "Building Information Modelling" OR "Industry 4.0" OR "AI" OR "Artificial Intelligence" OR "Digital Twin" OR "BMS" OR "Building Management System")* was used in titles, abstract or keywords of a publication. The search query resulted in a list of 407 papers from Web of Science and 421 from the Scopus database. Only journal papers written in the English language were considered as an inclusion criterion. However, the search process was not limited to the publication date, as most of the evidence in this domain is recent. After using the inclusion criteria, it resulted in 236 papers in Scopus and 188 in Web of Science. As some studies existed in both lists, duplicates were removed, and only 196 papers were retained. After careful screening of the title, abstract, only 32 remained for the in-depth review. Figure 1 illustrates the methodology followed in the scoping review.

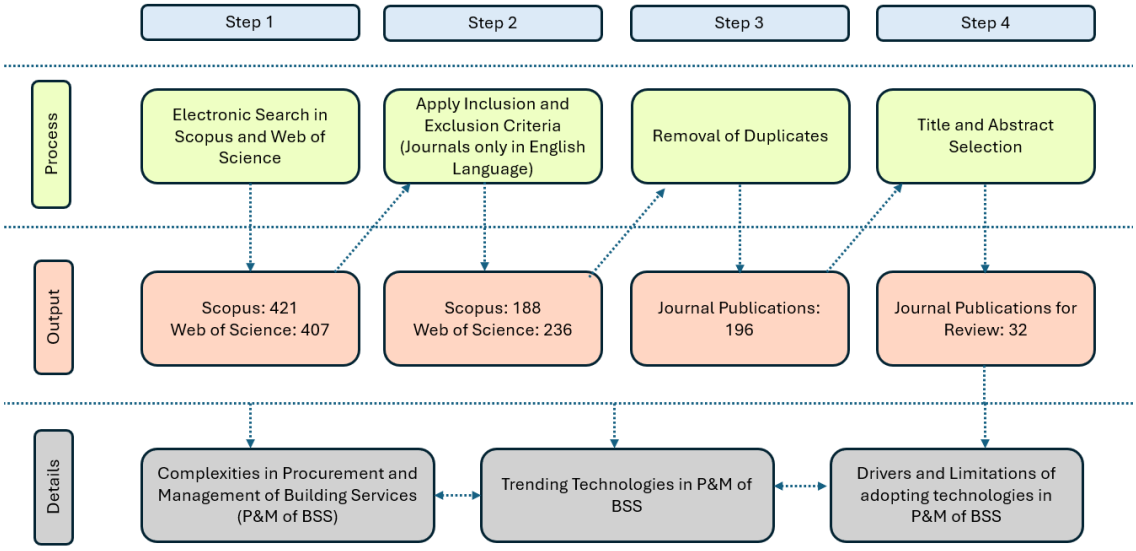

Figure 1: Research methodology adopted in the study

3. FINDINGS AND DISCUSSION

This section discusses the findings of the scoping literature review.

3.1 COMPLEXITY OF PROCUREMENT AND MANAGEMENT OF BUILDING SERVICES SYSTEMS

In general, procurement involves acquiring goods or services from external suppliers and includes activities such as requirement identification, source selection, quotation requests, and vendor evaluation (Boniface et al., 2024). However, the P&M of BSS extend beyond these conventional steps due to several factors, including the long lifecycle of systems, the involvement of multiple stakeholders, the need for specialised knowledge for installation, and strict regulatory and technical requirements. Table 1 summarises the complexities of building services from different perspectives. The areas in Table 1 were logically derived based on the literature review findings.

Table 1: Comparison of procurement and management of general building elements and building services systems

Identified Area	P&M of Building Services Systems	P&M of General Building Elements	References
(C1) Collaboration	These systems (e.g., HVAC, electrical, vertical transportation, plumbing, fire protection) are highly technical and interdependent, requiring precise integration with other building elements and subsystems. This complexity increases procurement challenges as specifications must align with performance criteria, regulatory compliance, and future adaptability.	Procurement of structural or architectural elements (e.g., concrete, steel, or finishes) has comparatively less technical integration and fewer interdependencies, making specifications and vendor selection more straightforward.	(Arora, 2023; Hassanain et al., 2019; Korman et al., 2003; Marsh, 2012; Shoesmith, 2010)
(C2) Approvals	Planning and Design require specialised knowledge, which leads to third-party consultants, builders and vendors. This process requires multiple back-and-forth approvals, which affects the schedule of the construction project.	More standardised designs and codes reduce the reliance on niche expertise.	(Abdelhameed & Saputra, 2020; Khan et al., 2023; Singh et al., 2018; Wu et al., 2022)
(C3) Design Requirements	BSS designs might include proprietary systems or vendor-specific solutions based on the intended functionalities and client requirements. Special subcontractors and manufacturers need to be selected through a tendering process for the installation.	More standardised designs and codes reduce the complexity of the designs. Subcontractor selection does not require high technical capacity.	(Akhil & Das, 2019; Rabb & Vesali, 2022; Smart Hospitals Project & Pan American Health Organization, 2020; Wan & Kumaraswamy, 2012; Wang et al., 2016)
(C4) Technical Calculations	BSS designs are more iterative, with frequent adjustments based on evolving requirements (e.g., load calculations and equipment specifications) demanding smooth collaboration.	Designs for structural and architectural components typically follow a more linear process with fewer iterations.	(Gurmu & Mudiyanselage, 2023; Smart Hospitals Project & Pan American Health Organization, 2020)

Identified Area	P&M of Building Services Systems	P&M of General Building Elements	References
(C5) Lifecycle Management	Requirements evolve over the building's lifecycle, from design, installation, commissioning, operation, and maintenance to eventual upgrades or decommissioning, ensuring the service continuity after the handover phase.	These elements typically have static specifications that end after the project handover or the defect liability period.	(Chauhan et al., 2022; Hu et al., 2016; Ni et al., 2021; Tyrrell, 2023)
(C6) Communication	The integration of BSS involves multiple stakeholders, including engineers, architects, consultants, contractors, and facility managers. Misalignment or lack of communication between these stakeholders can lead to delays, cost overruns, and performance issues.	While coordination is still necessary, the roles and responsibilities are often more clearly defined, and the integration is less complex.	(Rejeb et al., 2018; Tatum & Korman, 2000; Wan & Kumaraswamy, 2012)
(C7) Regulatory Requirements	Stringent regulations related to energy efficiency, safety, and environmental impact require meticulous documentation, testing, and approvals. Non-compliance can result in significant legal and operational risks.	These typically face fewer regulatory hurdles, and compliance tends to focus on structural integrity and material standards, which are easier to validate.	(Australian Building Codes Board 2021; Gossain, 2023; Greeno & Hall, 2009; Tyrrell, 2023).
(C8) Commissioning and Handover	The commissioning and handover of the BSS are complex, involve all stakeholders and often lie in the critical path of the construction project.	The construction of conventional elements is a well-established process in the construction schedule.	(Khan et al., 2023; Schneidera et al., 2015; Xie, 2024)
(C9) Procurement Management	BSS requires specialised procurement methods, such as performance-based contracts, due to its technical component.	Traditional (design-bid-build, design-build) and modern methods (Public Private Partnership, Engineering, Procurement and Construction) can be adopted.	(Aibinu & Papadonikolaki, 2016; Akhil & Das, 2019; Heydari et al., 2024; Kim & Kim, 2024; Mosley Jr & Bubshait, 2017)
(C10) Maintenance Management	Frequent disputes over maintenance contracts, service-level agreements (SLAs), extended warranties, and system upgrades are generated.	Limited post-construction claims, mostly related to structural defects within the liability period, are created.	(Ismail, 2021; Kumar et al., 2022; Remedial, 2022)

Identified Area	P&M of Building Services Systems	P&M of General Building Elements	References
(C11) Cost	High initial costs, coupled with unpredictable operational and maintenance costs, pose challenges in estimating. Also, delays due to custom manufacturing, technological obsolescence, and specialised installation requirements create risks in deliveries and quality.	Cost estimation is generally more predictable, and risks are limited to common issues like material shortages or weather delays.	(Akhil & Das, 2019; Cai et al., 2018; Johnson & Babu, 2020; Siren & Pennanen, 2014)
(C12) Technical Skills	Maintenance is a continuous process requiring specialised skill sets and tools. Lifecycle costs often exceed initial procurement costs, necessitating robust planning and resource allocations	Maintenance requirements are generally lower and less technically demanding, with costs concentrated upfront.	(Gurmu & Mudiyanselage, 2023; Hu et al., 2018; Khana et al., 2020; Smart Hospitals Project & Pan American Health Organization, 2020)
(C13) Future Extensions	Systems often need to be scalable and adaptable to accommodate future building expansions, changing user needs, or technological upgrades, complicating P&M.	These elements rarely require scalability or adaptation after installation.	(Gunasekara et al., 2021; Howkins, 2017; Ismail, 2021; Kumar et al., 2022; Remedial, 2022)

3.2 AVAILABLE TECHNOLOGIES FOR PROCUREMENT AND MANAGEMENT OF BUILDING SERVICES SYSTEMS

In response to these complexities, an adoption of systematic procurement and management (P&M) is required in Building Services Systems (BSS) using emerging technologies. The following section discusses the potential technologies which can be used in the P&M of BSS.

3.2.1 Building Information Modelling (BIM)

Building information modelling is a significant advancement in the construction industry, which digitally presents the building or infrastructure project's physical and functional characteristics. During the pre-construction planning stage, BIM plays a vital role in visualising the project, detecting potential conflicts and optimising the design. The 3D models generated by BIM can be used for compliance checking of building services systems and spatial requirements. This clash detection highlights the potential conflicts in the design phase, preventing expensive on-site variations (Shahruddin & Zairul, 2020). Further, BIM is used to generate accurate cost estimates and is linked with budgets so that project managers can make accurate decisions on project budgets (Pérez-García et al., 2021). Additionally, BIM can be linked with project schedules and stakeholder collaborations. This transformative approach enhances visualisation, streamlines coordination, and improves communication among stakeholders, leading to improved efficiency and reduced errors in building services projects. The capability of BIM extends beyond the initial phases of the projects. It can support the facilities management of BSS and lifecycle analysis, which enhances long-term project sustainability and operational efficiency. These insights are vital for decision-making, which seeks to optimise the resources and minimise the negative environmental impact. However, BIM adaptation faces some challenges, including high initial implementation cost, the requirement of expert knowledge of using the tool, interoperability issues with data formats and drastic workflow changes. Further, the data in the BIM models is not tamperproof, so it can be subjected to manipulation without any authorisation (Husin & Kristiyanto, 2024; Li et al., 2022; Ni et al., 2021).

3.2.2 Data Analytics and Artificial Intelligence (AI)

Data analytics and AI can be used for data-driven insights that guide strategic procurement and management of building services systems. Data analytics not only evaluate suppliers' performance but also uncover market trends, offering a holistic view of the procurement landscape. This understanding allows professionals to make better decisions on procurement strategies (Ibem & Laryea, 2014). On the other hand, AI improve the decision-making capabilities by predicting purchasing trends and optimising clients' requirements. Further, AI can automate repetitive tasks by reducing the number of intermediaries. AI can be used to analyse the contract documents and identify variations with dynamic changes in site operations (Alaloul et al., 2020). Moreover, in the post-installation phase, AI-powered systems are enabled to monitor predictive and preventive maintenance measures without human involvement. However, the adoption of AI presents several limitations. One major challenge is the requirement for large, high-quality datasets to support predictive decision-making. In practice, data within the construction sector is often fragmented across multiple software platforms, making it difficult to consolidate, trace, and extract the necessary information for effective AI

model training. Additionally, many AI models, particularly deep learning algorithms, operate as "black boxes," offering limited interpretability of the underlying decision-making processes. This lack of transparency reduces stakeholder trust and confidence in AI-generated outcomes. Furthermore, ethical concerns arise regarding the use of sensitive or confidential data, particularly in relation to data security, ownership, and privacy protection (Francis & Zhou, 2025; Perera et al., 2024).

3.2.3 Digital Tools for Communication and Collaboration (DTC)

Before Procurement 4.0, construction project teams were challenged with coordinating and collaborating with diverse stakeholders such as architects, contractors, subcontractors, manufacturers and installers, especially in the planning and design phase of the building services systems (Chopra, 2018). The invention of numerous software with cloud-based systems has significantly improved stakeholder integration and promoted teamwork. Cloud-based platforms, such as file-sharing software and email communication software, facilitate real-time access to essential project data, thereby reducing the likelihood of miscommunication and ensuring everyone is aligned with project objectives and requirements (Puolitaival et al., 2018). Especially in the planning and design phase, numerous documenters are transferring among stakeholders, which is difficult to handle without a real-time update mechanism. Further to above, advanced functionalities such as version control, document tracking and permission-based access ensure data accuracy, support traceability and maintain consistency, which helps project teams to maintain a clear audit trail and ensure that everyone is working with the most updated document. A key challenge of using DTC is the fragmentation and lack of interoperability across platforms. This fragmentation makes it difficult for users to trace data origins, leading to frustration and a lack of accountability, as it becomes unclear who generated or modified specific information. In building services systems (BSS), data manipulation is a recurring issue, particularly during the maintenance phase, further undermining data integrity. If a system does not effectively prevent data manipulation, users are unlikely to have confidence in its reliability and integrity. Additionally, data security concerns and inconsistencies in stakeholder adoption of different software platforms exacerbate these limitations.

3.2.4 Blockchain (BT)

Blockchain technology represents a new era of security and transparency within procurement processes. Its integration into construction procurement workflows ensures secure, transparent, and tamper-proof execution of transactions (Jeoung et al., 2022). Moreover, the transactions recorded in the blockchain are immutable thus, the data in the blockchain is secure. The use of smart contracts in blockchain further automates procurement activities, reducing reliance on intermediaries and lowering associated costs and delays. This automation not only streamlines operations but also accelerates transaction timelines, contributing to improved project efficiency. Additionally, the distributed ledger in blockchain architecture provides real-time visibility into procurement actions, ensuring traceability and accountability while mitigating the risk of fraudulent activities (Mahmudnia et al., 2022). Blockchain support in building services systems in the maintenance period as well. Inspection data can be securely recorded on the blockchain, ensuring tamper-proof documentation that is free from manipulation or human bias. This immutable record-keeping mechanism serves as a reliable audit trail, supporting the development of asset condition reports at the end of the system’s lifecycle.

This transparent approach supports data-driven decision-making, allowing construction organisations to shift smoothly throughout the procurement lifecycle. Despite the benefits of blockchain, the practical implementation of it in P&M of BSS is not without challenges. Integration of blockchain with existing legacy systems is complex and requires substantial architectural changes, as it operates as an underlying technology. Moreover, P&M of BSS generate huge data, leading to scalability and performance limitations, particularly in balancing on-chain storage with off-chain data processing. The deployment of smart contracts also raises regulatory and legal uncertainties, especially concerning contract enforceability, liability attribution, and compliance with regulations (Hijazi et al., 2021).

3.2.5 Digital Twin (DT)

A digital twin, also called a data twin, is a dynamic digital representation of a physical asset created by gathering real-world data through technologies such as 3D laser scanning, drones, IoT-enabled sensors, cameras, and other smart devices. When combined with Artificial Intelligence (AI) and the Internet of Things (IoT), digital twins can learn and autonomously update to mirror changes occurring in their physical counterparts. These models capture a wide range of asset properties, including spatial orientation, operational status, and environmental interactions. Synchronisation between the digital and physical environments is affirmed with BIM, 3D modelling software, point cloud data, and real-time sensor feedback. Digital twins significantly enhance the analytical power of BIM by transforming static models into intelligent, "living" systems capable of real-time monitoring and decision support. They enable construction teams to gain granular insight into each building service system, facilitating proactive maintenance, performance optimisation, and lifecycle assessment. This arrangement of physical and virtual environments allows stakeholders to visualise real-time asset conditions and simulate operational scenarios before implementation. For facility owners and managers, digital twins are useful for comprehensive asset monitoring, enabling the digital reconstruction of physical environments and supporting data-driven decision-making throughout the asset lifecycle**.** However, DT application involves high set-up and maintenance costs with many resources. Further, it requires real-time data inputs, which is challenging with IoT sensors in a construction environment. Additionally, modelling the dynamic behaviour of complex building systems remains technically demanding due to limited standardisation across platforms (Opoku et al., 2021).

3.2.6 Building Management Systems (BMS)

Building Management Systems (BMS), also called Building Automation Systems (BAS), are centralised, computer-based control systems designed to monitor and manage a building service infrastructure. Acting as the central control point for all facilities within the building, the BMS enables facility managers to remotely control and adjust equipment performance through desktop or mobile interfaces, without physically walking to each building floor and room to shut down, switch on or manually adjust the systems.

BMS enhances building performance by real-time data acquisition and automated control algorithms while reducing energy consumption and operational costs. The system plays a critical role in sustainable facility management by optimising resource usage and maintaining predefined environmental conditions. Additionally, modern BMS platforms often incorporate data analytics, fault detection, and predictive maintenance capabilities, further supporting strategic decision-making and extending asset lifespan. The key

challenges associated with Building Management Systems (BMS) include limited flexibility for custom integration and reliance on expensive proprietary platforms. These systems often involve complex setup and configuration processes, and they require ongoing technical support for effective operation and maintenance.

Table 2 illustrates the summary of the potential technologies in addressing the identified complexities in P&M of BSS.

Table 2: Technological solutions to identified complexities

Complexities in P&M	Features of the technology to address the complexity in P&M	BIM	AI	DTC	BT	DT	BMS
(C1) Collaboration	BIM enables centralised design data, Digital collaboration tools improve real-time coordination, and Blockchain ensures transparency and traceability of design changes.	√		√	√		
(C2) Approvals	Blockchain ensures immutable approval logs and digital signatures, BIM helps visualise compliance for approvals, AI assists in document classification and automated review workflows.	√	√		√		
(C3) Design Requirements	BIM allows for coordination of proprietary systems and data-rich object representation; AI supports selecting optimal systems, Digital Twins simulate performance and refine requirements early in the design phase.	√	√			√	
(C4) Technical Calculations	AI automates load and energy calculations; BIM integrates technical data in design, IoT provides real-time performance data that informs calculation accuracy.	√	√			√	
(C5) Lifecycle Management	Digital Twins enable ongoing monitoring, BMS manages and adjusts systems with real time data with IoT and manages lifecycle.					√	√
(C6) Communication	Cloud-based tools facilitate cross-stakeholder collaboration, BIM provides a visual single source of truth for technical and functional data. Blockchain enhances the trust among parties.	√		√	√		
(C7) Regulatory Requirements	BIM tracks compliance throughout the design; Blockchain secures compliance records, AI detects non-conformities automatically.	√	√		√		
(C8) Commissioning and Handover	BIM and Digital Twins support accurate as-built records and operational handovers, Blockchain secures commissioning documentation and responsibilities.	√			√	√	
(C9) Procurement Management	Blockchain supports smart contracts and procurement transparency, AI assists in supplier selection and tender evaluation	√	√		√		

Complexities in P&M	Features of the technology to address the complexity in P&M	BIM	AI	DTC	BT	DT	BMS
	(Predictive analytics). BIM provides clear designs and specifications for procurement.						
(C10) Maintenance Management	BMS automates monitoring, fault detection and energy analytics. IoT provides real-time fault data with remote monitoring, Digital Twins simulate maintenance needs and optimise schedules (Performance forecasting), Blockchain maintains accountable and immutable maintenance records.	√				√	√
(C11) Cost	AI predicts cost overruns, BIM improves cost estimation through model-based quantity take-offs, Digital Twins help simulate long-term operational costs.	√	√			√	
(C12) Technical Skills	AI and digital platforms reduce dependency on manual skills, Digital Twins support remote diagnostics, IoT simplifies complex data gathering for technicians. Further Digital twin supports scenario testing.		√			√	
(C13) Future Extensions	BIM allows scalable modular designs, Digital Twins forecast performance under future changes, IoT provides feedback for reconfiguration. Blockchain provides all historical records for knowledge management.	√			√	√

4. CONCLUSION AND RECOMMENDATIONS

This study highlights the complexities involved in the Procurement and Management of Building Services Systems (P&M of BSS) due to their lengthier lifecycles, the engagement of multiple stakeholders, and the requirement of specialised technical knowledge. A scoping literature review was conducted with 32 journal papers and identified complexities in P&M of BSS in terms of collaboration, approval process, design requirements, technical calculations, lifecycle, communication, regulatory requirements, etc. The findings highlighted the importance of systematic, technology-driven approaches to address these complexities.

Technologies such as BIM, blockchain, digital communication platforms, digital twins, and building management systems have been identified as trending technologies which have the potential to streamline workflows, enhance transparency, and support informed decision-making across different phases of the building services systems lifecycle. It is important to emphasise that these technologies should go hand in hand with each other for better performance. Further, there are limitations of each technology which need attention before the adaptation, including technical, environmental, and people considerations.

Given the limited research focused specifically on building services systems procurement and management, this study contributes to bridging that gap by identifying the complexities and proposing potential technological solutions. The findings are intended to assist project stakeholders, specifically decision-makers, in selecting appropriate digital tools to manage complexity more effectively. By promoting technology adoption, the research underscores the potential for improving efficiency, collaboration, and overall project success in the construction industry, leading to the achievement of sustainable development goals. Future research can focus integration of these technologies for systematic P&M of BSS.

A REVIEW ON CIRCULAR ECONOMY AND ITS SYNERGY WITH INDUSTRIAL SYMBIOSIS

Angel Lokuge[1], Gihan Anuradha Tennakoon[2] and Udayangani Kulatunga[3]

ABSTRACT

The construction industry, a major contributor to global material consumption and environmental impact is also pivotal for economic growth and job creation. Hence, transitioning to concepts like Circular Economy (CE) and Industrial Symbiosis (IS) offers a sustainable pathway in reinforcing the industry by mitigating the negative impacts. CE emphasizes principles like reduce, reuse and recycling to close loops, while IS fosters this through cross-industry collaboration by repurposing waste and by-products. This study explores synergies between CE and IS in the context of the construction industry to address the implementation gaps of the two concepts. Through a narrative literature review, this study analyses definitions, and principles to CE adoption in construction sector, such as fragmented regulations, high costs, technical limitations. Moreover, findings reveal that IS is a critical enabler for CE in bridging implementation gaps. This is by facilitating material exchanges between different industries This study also explored current practices of these concepts in various regions. Though the studies prove this synergy, between CE and IS, it was also highlighted that practical challenges persist, at the same time underscoring role of the IS concept due to the lack of trust and systemic linkage. In concluding the research, it was emphasized that policymakers and industries must prioritize in creating and working on collaborative frameworks, standardising regulations while ensuring the construction sector aligns with sustainable development goals.

Keywords: *Circular Economy; Construction Industry; Industrial Symbiosis; Sustainability; Waste Management.*

1. INTRODUCTION

Construction industry with its special features offers unique opportunities to a country, significantly contributing to the economic growth, creating job opportunities, and simulating development processes through projects such as infrastructures. However, the construction industry is known to be among the most material-intensive sectors globally, consuming massive amounts of raw material and generating massive amounts of waste. In the European Union, for instance, the construction industry consumes 1.2 to 1.8 million tons of raw material annually. In Netherlands, constructions industry accounts for approximately 50% of the overall material consumption (Yu et al., 2021). The situation

[1] Academic Instructor, Department of Quantity Surveying, SLIIT, Sri Lanka, angel.o@sliit.lk
[2] Senior Lecturer (On Contract), Department of Building Economics, University of Moratuwa, Sri Lanka, anuradhat@uom.lk
[3] Professor in Building Economics, Department of Building Economics, University of Moratuwa, Sri Lanka, ukulatunga@uom.lk

is not all that different in the Asian region as well. Even though compared to Northern Europe and North America, many regions of Asia have a low material consumption, it still accounts for a considerable amount (Schiller & Roscher, 2023). Overall, the construction and building sector annually incorporates about 40% of the over 90 billion tonnes of raw materials extracted from the earth (Valentini, 2023). Further, the global consumption of building materials has tripled from 6.7 billion tons to 17.5 billion tons during the period from 2000 to 2017 (Huang et al., 2020). According to the global status report for building and construction, this sector significantly contributes to global climate change while accounting for about 21% of global greenhouse gas emissions. It also states that buildings were accountable for 37% of energy and carbon dioxide (CO_2) emission and 34% of global energy demand specifically in 2022 (United Nation Environment Programme, 2024). Most importantly, the process from extraction to manufacturing of these building materials itself has resulted in almost 90% of the life cycle environmental pollution.

These staggering environmental impacts has brought the need for a transformation towards Circular Economy (CE), a principle which the Ellen MacArthur Foundation defines as an industrial system which brings in a transition from linear "take-make-waste" model into a circular approach (Ellen MacArthur Foundation, 2013). One of the main reasons for a major part of waste generation is the linear economy, whereas in a CE, the circular approach can take the role and work in reducing waste generation. As a sustainable concept, CE shows a significant potential in actualization of the sustainable development goals. Therefore, CE was placed as the heart of sustainable development (Ogunmakinde et al., 2022). Hence, CE has the potential to effectively address the aforementioned issues that the construction sector is struggling with due to the environmental, social and economic pillars globally.

However, this transition towards CE requires practical measures. The actions that stand out among the current CE practices used in the industrial sectors are almost limited in aiming at recycling and reusing within a small range, usually within an organisation. In addition, there are number of studies conducted related to the importance of CE concept, even though the practical implementation of it seem to be lacking. However, recently, the necessity for the implementation of cross-cutting intersectoral networks have been raised as a way forward in transitioning towards a CE (Oskam et al., 2021). Therefore, rather than working in isolation, stronger connections and interactions between sectors have been recognized as important to improve the effectiveness of recovering and reusing materials. To ensure this, Industrial Symbiosis (IS), which focuses on intersectoral exchange of waste or by-products, should be uplifted and implemented universally (Castellet-Viciano et al., 2022). While the theoretical knowledge on CE and IS are well-established, and their individual benefits are acknowledged, yet there is notable gap in literature that explicitly addresses their combined potential to overcome the implementation barriers within specific industrial context, particularly the construction sector. Existing studies often discuss and explore these two concepts in isolation or provide a general overview of their synergy in various other context. However, this synergy has not been explored from a construction industry perspective

This study, therefore, aims to explore the CE and IS concepts and their synergy in the construction industry. This includes the lessons learned throughout the past decades by different countries, and both advantages and disadvantages experienced along with

studying how to fill in the gaps of CE implementation through IS. Accordingly, to achieve the aim of the research, three objectives were formulated as follows:

1. Objective 01: To explore both CE and IS concepts.
2. Objective 02: To find the similarities and differences between CE and IS.
3. Objective 03: To create synergy in bridging the gaps in implementation of CE through IS in the construction context.

2. RESEARCH METHODOLOGY

The research aim was set to explore the concept of CE and its synergy with IS. To fulfil the aim, a narrative literature review was conducted. Selected existing literature sources were use to collect data for this study. Literature sources including journal articles, books and conferences papers were used to gather in-depth knowledge regarding the study area. Moreover, reports, news articles and well-established websites were also used to provide statistics to reinforce the findings. The data was collected by searching key words strings of "Circular Economy", "Industrial Symbiosis" and "Circular Economy" AND "Industrial Symbiosis" in combination. This method made it possible to explore more broadly and openly different sources related to the research topic. The search targeted scientific databases such as Google Scholar, Scopus, and Web of Science with an interest in literature on IS, CE and their integration with specifically focusing on the construction industry. During the process peer-reviewed journal articles, conference papers, and institutional reports were given a priority. Grey literature from Government reports, industry websites, and reputable news sources, gathered through an internet search, were also utilized to ensure that current viewpoints and actual scenarios were captured. This approach which included gathering data from a range of literature sources facilitated producing a wide overview of the field of study, beyond solely academic writing (Snyder, 2019).

3. CIRCULAR ECONOMY (CE)

The concept of the CE has been studied over the past decades and is now gaining significant traction among both researchers and practitioners. According to research, there is no specific single originator or an origin for the CE concept. Yet, many has contributed to bringing up this concept. Some of the significant contributors are Michael Braungart, a German chemist; John Lyle, a U.S. professor along with his student William McDonough and Walter Stahel, an economist and an architect, respectively. Later, in the 1990s, the CE concept was popularized, especially in China, as a response to natural resources scarcity and economic growth. Recycling was a noticeable factor within this concept (Winans et al., 2017). The CE practises in China, which were well-recognized with '3R" concept, was originated from Germany and Japan, where there was a greater desire in forming a more closed loop society (Geng & and Doberstein, 2008). Since there have been various countries and various researchers showing interest towards the CE concept with different views, this section intended to explore the concept of CE in detail, including its definitions, principles, benefits and its applicability for the construction industry.

3.1 DEFINITIONS AND PRINCIPLES OF CIRCULAR ECONOMY

There are various definitions for CE that can be found in different research papers, and minor changes can be seen based on aspects such as the year of introduction, the

researchers, and the study contexts. Some studies have also attempted to collate these different definitions to develop a common definition for CE. Table 1 presents studies identified through an in-depth search of available resources.

Table 1: Existing studies on different CE definitions

Authors	Title	Definition
Kirchherr et al., (2017)	Conceptualizing the circular economy: An analysis of 114 definitions	Acknowledge that CE understanding can be broader than a definition. They define CE as "an economic system that replace the 'end-of-life' concept with reducing, alternatively reusing, recycling and recovering materials in production/distribution and consumption processes." It operates at the micro level (products, companies, consumers), meso level (eco-industrial parks) and macro level (city, region, nation and beyond), with the aim to accomplish sustainable development, thus simultaneously creating environmental quality, economic prosperity and social equity, to the benefit of current and future generations.
Geisendorf & Pietrulla (2018)	The circular economy and circular economic concepts-a literature analysis and redefinition	Stated that "The circularity indicators of the Ellen MacArthur Foundation (2013) only capture the product and company level but fail to provide ideas for the macroeconomic level." They have revised the CE definition with distinguishing between core characteristics of a circular economy and framing conditions enabling its implementation. Their revised distinguish how the most common concepts mentioned by others are situated in different dimensions like efficiency/zero waste target, industry/service oriented, or micro/macro scope.
Awan, et al., (2020)	A Literature Analysis of Definitions for a Circular Economy .	Twenty-eight definitions were taken into consideration covering a period from 1999 to 2019. This analysis revealed that up to this period, stakeholder perspective and resilience were not included explicitly in the definitions. Ultimately it stated, "Circular Economy (CE) is an activity, set of process for reducing the material used in production and consumption, promoting material resilience, closing loops and exchange sustainability offering in such a way that maximize the ecological system."
Alhawari et al., (2021)	Insights from Circular Economy Literature: A Review of Extant Definitions and Unravelling Paths to Future Research	Study focused on capturing the key aspect from the definitions that varied in their coverage and provide better understanding of the CE concept. The authors have defined CE

Authors	Title	Definition
		in the following manner considering the organizational perspective - "CE is the set of organizational planning processes for creating and delivering products, components, and materials at their highest utility for customers and society through effective and efficient utilization of ecosystem, economic, and product cycles by closing loops of concerning resource flows."
Kirchherr et al., (2023)	Conceptualizing the Circular Economy (Revisited): An Analysis of 221 Definitions	The authors believed a clearer, more practical and relevant CE conceptualization can aid in maintaining proper connection between CE practice and research. Through their framework used to examine 221 definitions they also expected to see whether they are universally or locally tailored. This study focused on contributing an updated systematic analysis of CE definitions, while aiming to illustrate where the academic fields currently sit on its own understanding about this concept. They recognized and stated that final definition may never materialize. Moreover, they stated that depending on the regular shifting state of environmental conditions, technologies and economic and socio-political context the definition of CE is more likely to be on a state of evolution.
Sardianou, et al., (2024)	What are the key dimensions that CE emphasizes on? A systematic analysis of circular economy definitions	The authors found that CE definitions have focused on "waste management", "resource scarcity" and "recycling" activities. They also stated that "CE is typically viewed through the lens of waste management, emphasizing the need to reduce unnecessary demand, in addition to promoting efficient resource and product usage." The authors have not provided a specific definition but have analysed several existing definitions. They found and highlighted that "waste" and "recycling" as the central concepts of CE.

3.2 CIRCULAR ECONOMY IN THE CONSTRUCTION INDUSTRY

The concept of CE offers a sustainable solution to the issues created by the linear material consumption trend which is "take, make, dispose" in the construction industry. CE seeks to maintain the material value at the highest point by following practices such as reducing, reusing, and recycling (Andrews, 2015; Lieder & Rashid, 2016). Academic definitions of CE in construction have converged around several key principles like reuse, recycle, recover, and all-together-framework like 3R and 4R (Kirchherr et al., 2023). Over the past decades, a significant transferring has been occurring in the industry, with the CE model adoption. It made a huge change in providing greater potential to reduce both

resource extraction and waste generation for the construction industry. However, as stated by Benachio et al., (2020), there is a greater level of awareness which has been found within CE in the built environment research area about the need of change to a CE from the traditional linear economy concept. Yet, the real-world practitioners argue on the lack of standardized practices and methods to aid in proper implementation of CE in construction industry.

4. INDUSTRIAL SYMBIOSIS AS A SYSTEMIC ENABLER FOR CIRCULAR ECONOMY

The transformation from linear to circular economy needs efforts from everyone and especially from industries, as they play a vital role in transformative consumption and production patterns. European Commission being one of the practitioners had put their focus on different recommendations with measures for the transformation of the industrial sector to maximize recyclability and durability of materials, and through that, ultimately reduce the environmental impact. The initial step of industrial sector in CE strategies is aimed at implementing action plans like using recycled and reused products within production systems (Sardianou et al., 2024). Yet, as the CE concept move further towards seeking advanced criteria, in early 2000s they implemented an action plan transversally rather than vertically along the supply chain (Neves et al., 2020).

Hence, the need of cross-cutting intersectoral networks had arisen to ensure the sustainability of the industrial sector. IS is a subsector within industrial ecology that studies the flows of energy and materials. It has now evolved to an extent where it is viewed in broader terms rather than in isolation. As a result, it tries to interconnect the industries and their process in maximizing the use of energy and materials (Wadström et al., 2021). On the other hand, with the CE concept remarkably being more conceptualized and defined, IS also had started gaining more attention by companies to reduce waste emissions along with an urge to find alternatives for primary resource consumption. Thereby, IS was considered as one of the effective solutions that brings down the primary input consumption and environmental impact of waste emissions (Yazan et al., 2016). Chertow (2007) defined IS as "engaging traditionally separate industries in a collective approach to competitive advantage involving physical exchange of materials, energy, water, and byproducts. The keys to IS are collaboration and the synergistic possibilities offered by geographic proximity" (Chertow, 2007). According to the location and the case, the specificity of IS may change. Most importantly, IS only succeeds if companies are willing to take a risk and at the same it lasts only if both the waste supplier and waste user has build-up trust among them (Yap, 2005). Regardless of individual efforts, companies and industries must get together and interact to receive the maximum results of their actions and guarantee a smooth, effective and efficient flow of recovered and reused materials. To achieve this, IS, which is being practiced in some of the European countries must be universally implemented (Castellet-Viciano et al., 2022). According to Martin et al., (2015), IS can be identified as an effective enabler in accomplishing the principles of the CE.

4.1 DEFINITIONS AND PRINCIPLES OF INDUSTRIAL SYMBIOSIS

IS promotes physical exchanges of wastes, energy, and by-products among traditionally separated industries in a collective manner (Chertow, 2007). It is a sub-field of industrial ecology, which is now gaining attention through literature as a key strategy being

supportive for the transition towards CE (Fraccascia & Giannoccaro, 2020). The main principle here is that two parties in particular, identified as waste producer and waste user, get together to establish a relationship where one would exploit the waste of the other party to make a new product or to replace an input in the production process (Patricio et al., 2022; Chertow, 2000). Chertow (2000) had defined the IS as "engaging traditionally separate industries in a collective approach to competitive advantage involving physical exchange of materials, energy, water, and by-products. The keys to industrial symbiosis are collaboration and the synergistic possibilities offered by geographic proximity". This definition is widely being disseminated (Neves et al., 2020). A more recent definition by Haq et al. (2021) defines IS as "a collaboration scheme for competitive advantage where industrial trade is essential to developing a sustainable future because it involves resources, energy, water, and/or by-products being exchanged among various industries".

4.2 SYNERGIES BETWEEN CIRCULAR ECONOMY AND INDUSTRIAL SYMBIOSIS

CE concept's first roots run back to almost sixty years early consists of a fundamental part similar to Green Economy and industrial ecology, where IS is a sub-field of the industrial ecology. According to Andersen, (2007), IS seeks to optimize the management of the flow of materials, energy, water by-product, and ultimately to enhance the linear chain of consumption and production just as the CE concept. IS in particular, having a string to the CE, focus on operating at the inter-firm level (Yazan et al., 2016). As a result, IS has been identified as great potential component in facilitating CE by the European Commission (Álvarez & Ruiz-Puente, 2017).

4.2.1 Similarities and Comparative Analysis between Circular Economy and Industrial Symbiosis

Further to above findings from various literature, this section provides an overview of the most relevant similarities and differences between the two concepts, CE and IS, as depicted in Table 2.

Table 2: Similarities between circular economy and industrial symbiosis

Similarities between CE and IS
Aims to integrate the principles of environmental sustainability.
Foster material circularity to ensure more efficient usage.
The idea of waste can be repurposed is central in both.
Thrives to build linkage and relationships in different level of degree.
Contribute and encourage in local collaboration, job creation and cost saving.

The following Table 3 further provides a comparison on the key aspects of CE and IS concept.

Table 3: Comparative analysis between CE and IS
Source: Adapted from Vargas-Merino et al., (2022), Chertow & Park (2016) and Neves et al., (2020).

Factor	Circular Economy	Industrial Symbiosis
Main Goal	Slow down the scarcity of natural resources while minimizing environmental	Collaboration between industries to exchange materials, waste,

Factor	Circular Economy	Industrial Symbiosis
	damage through reducing pollutions.	energy and by-products to reduce environmental impact.
Research area	A wider range of recovery system	Generally, the direct physical exchange of materials, energy and by-product through pipelines system
Focus/Emphasizes on	Materials and products of all kinds	Largely industrial waste and by-product
Bottomline of the Term	Encourage resource efficiency and reduce waste through recycling	Enhance industrial collaboration and facilitates resource sharing.
Mainstream	Minimization of resource extraction; minimize waste	Waste-to-Resource, Inter-industry collaboration
Fundamental Principles	Developing imperative of sustainable development R; 3Rs improved to 9Rs	Cross-Sector collaboration, Sharing among waste producer and waste user

4.2.2 Industrial Symbiosis to Address Gaps in Circular Economy Implementation

CE is well-known to be a broader concept that tries to bring out the sustainability. In fact, the system-level approach of CE has been organized into three levels, named as the macro, meso and micro level. Each level has gaps which are needed and are being address. As the Figure 1 below elaborates, along with our key consideration on both levels of CE and IS, has been found go to hand in hand. In fact, IS has the potential to fill the gap within a wider approach to fill the one of the gaps of CE in practical implementation (Palagonia et al., 2025).

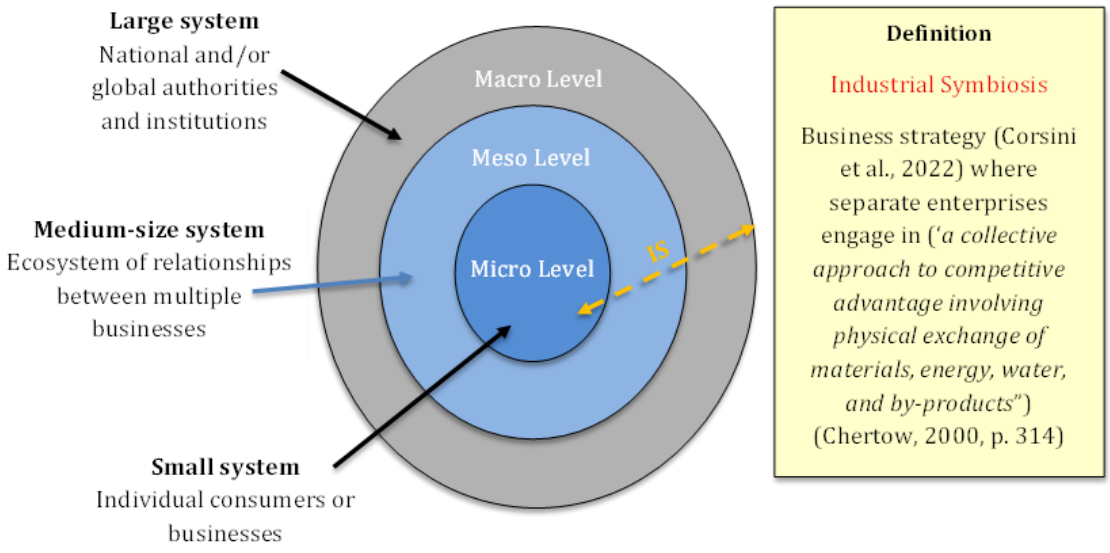

Figure 1: The industrial symbiosis within circular economy system level
Source: (Palagonia et al., 2025)

4.2.3 Collaborative Opportunities between Construction and other Industries

Park et al. (2015), had studied nine case resources circulating under IS development, where those projects delivered major benefits in Korea without a requirement of any investments. For instance, heat transfer salt which has reach the end-of-life stage in petrochemical process was repurposed in an easy manner as descaling salt for stainless steel. In another case, a waste organic solvent was directly used as a paint ingredient. For this no extra process was needed. Moreover, there have been IS activities seen in Europe as well regardless less attention in the literature related to this area. The European commission had introduced a revised CE package as an action plan for the CE where they refer the role of IS in focusing on the concept where "*waste or by-products of one industry to become inputs for another"* (Domenech et al., 2019). There has been waste recovery practice through IS found in two construction projects in Brazil. Through this it was found that those two project had 9% and 30% of waste was recovered through IS (Freitas & Magrini, 2017).

4.2.4 Conceptual Framework for Bridging Circular Economy Gaps through Industrial Symbiosis in the Construction Sector

According to the findings, a conceptual framework is proposed in Figure 2 which illustrates how the IS enables the implementation of CE principles within the construction sector by bridging the gap.

At the base of the framework, lies the construction industry which is traditionally resource-intensive and operates under a largely linear model of "take-make-dispose". Regardless, the increasing recognition of CE principles like reuse, recycling, and resource efficiency, there is a clear and greater implementation gap that hinders their full adoption in practice. Hence, the "gap" has been positioned at the centre of the framework representing the disconnection caused by barriers such as fragmented regulations, limited collaboration, technical challenges and high cost. The framework highlights that IS can effectively address this gap along with the proper contribution from Strategic/Policy Layer and Industry Actors. Through encouraging collaboration between different industries, IS facilitates the exchanges and repurposing of material, energy, and by-product transforming waste from one process into valuable input of another.

Finally, the goal is presented on top of the framework, which is an improved CE in the construction industry. As a result, the construction industry can move beyond isolated efforts and adopt more systemic, sustainable practices that align with the broader goals of environmental and sustainable development.

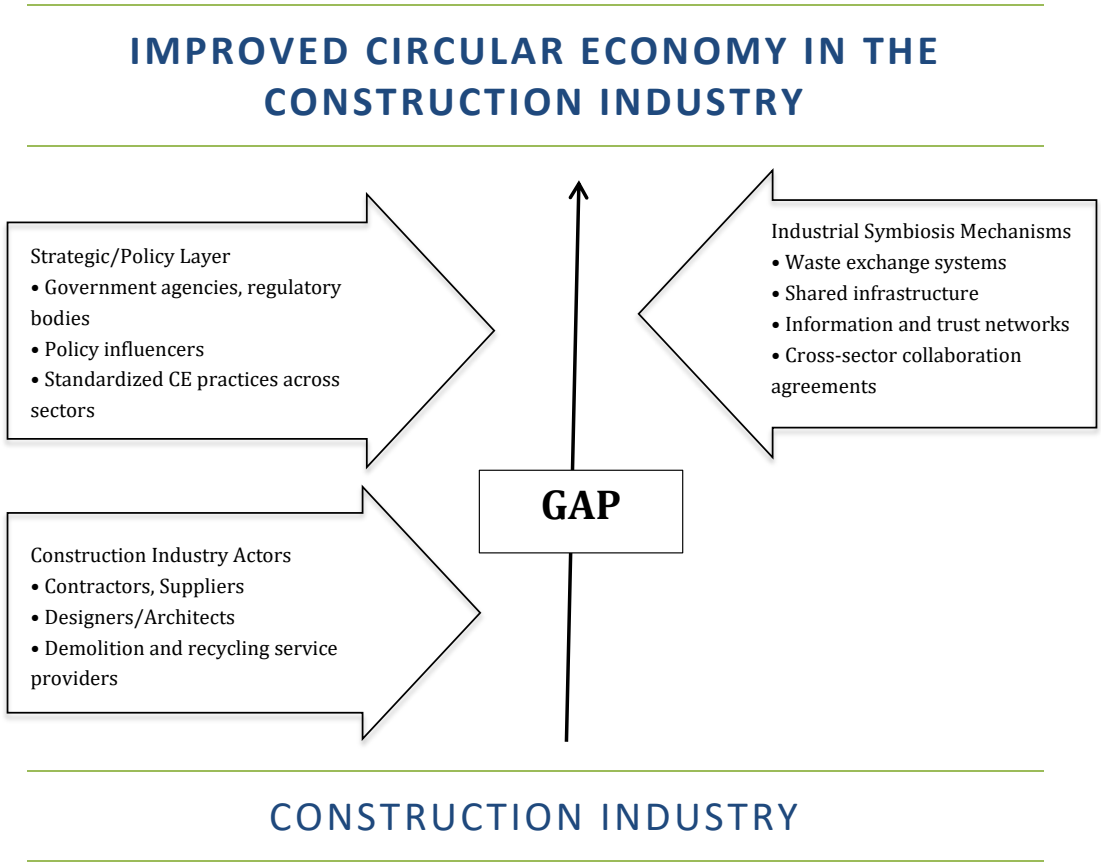

Figure 2: Conceptual framework for bridging circular economy gaps through industrial symbiosis in the construction sector

5. CONCLUSION

At present, CE is gaining attention increasingly as one of the promising solutions to address the environmental issues and the challenges of resource depletion. It was also found that even though CE has the potential to deliver significant environmental, economic and social benefits, it also includes gaps that has impacted on the proper and effective implementation of the concept in terms of all three levels (macro, meso, and micro). IS has the potential to connect within wider approach of CE and shift towards a multilevel framework. Studying about the synergies between CE and IS can help in better understanding the concepts and their effective implementation for beginners. Among the many definitions, understanding the concepts in an analytical manner and comparing the two concepts based on their similarities and differences, this study aimed at building awareness about the linkage between the two concepts. Through this narrative literature review, the authors presented various definitions on the concepts and similarities of both the concepts, where it was clear that CE and IS has goals in-line, except that CE is a broader concept than IS. The findings of this study highlights that IS directly addresses several crucial implementation gaps in CE, such as lack of systemic linkages, fragmented material flows and challenges faced in establishing cross-sectorial collaboration. Considering that this study provides evidence for the potential of IS in filling implementation gaps within CE, it would be a great contribution to study on the

mechanism to initiate this and recommend frameworks for better progression. The construction industry must see to it that they are actively seeking and establishing collaborative partnerships for material and energy exchange. This can be achieved through fostering trust and investing in infrastructure that supports inter-firm resource flows. Policymakers may boost this process through developing and enforcing regulatory frameworks and incentives that may specifically promote IS networks within the construction industry. It could include tax breaks while researchers focus on developing practical tools and guidelines to facilitate the formation and management of IS networks.

A SCOPING REVIEW OF CONSTRUCTION SMES: GLOBAL VS LOCAL

M.R.I.U.K. Ratnayake[1], M.R.D.P. Wijerathna[2], K.A.T.O. Ranadewa[3] and B.A.K.S. Perera[4]

ABSTRACT

The small and medium-sized enterprises (SME) sector is a significant driver of economic growth, significantly contributing to employment and gross domestic product (GDP) worldwide. However, Sri Lankan construction SMEs are lagging behind compared to those in other countries, where innovative legal frameworks and good practices have supported SME development and competitiveness. Learning from these global practices presents an opportunity to strengthen the local SME sector. Therefore, this study aims to investigate SMEs in local and global contexts comparatively. It explores SME definitions, legal provisions, and their role in economic development, while examining international best practices to enhance SME performance and resilience in Sri Lanka. A scoping review, supplemented by manual data analysis, reveals the absence of a universal SME definition and dedicated legislation, particularly in the construction sector. A comparative analysis of SME definitions across India, Japan, Europe, and Sri Lanka highlights varying approaches, often based on multiple criteria. Sri Lanka lacks dedicated SME act, relying instead on a policy framework and general legislation, with no specific provisions for construction SMEs. The study emphasises the vital role of SMEs in economic development as incubators for larger firms, drivers of employment and innovation, and contributors to social mobility and international trade. Their significance in economic recovery is examined, along with a review of legal frameworks, comparing dedicated SME acts with broader policies, including the current strategy of Sri Lanka. To support SME growth, the study proposes targeted legal provisions, digital transformation, e-commerce promotion, innovation support, and improved access to global markets.

Keywords: *Definitions; Global; Legal Provisions; SME Contractors; Sri Lanka*.

1. INTRODUCTION

The construction industry is crucial for driving the economic growth of a country and serves as an indicator of development (Ahmed, 2017; Peter et al., 2019). In most countries, this sector consists of a small number of large firms alongside a substantial proportion of small and medium-sized enterprises (SMEs) (Tezel et al., 2018). Despite the importance of SMEs, which is evident globally, there is no official definition which

[1] Undergraduate, Department of Building Economics, University of Moratuwa, Sri Lanka, ratnayakemriuk.21@uom.lk
[2] Lecturer, Department of Building Economics, University of Moratuwa, Sri Lanka, dewminir@uom.lk

[4] Senior Professor in Quantity Surveying, Department of Building Economics, University of Moratuwa, Sri Lanka, kanchana@uom.lk

is universally followed. The most common indication is by the number of employees, and there are certain other parameters that are used to define SMEs as well (Economic and Social Commission for Asia and the Pacific [ESCAP], n.d.). According to Acar et al. (2005), the term SME is interpreted differently across regions and countries, with the number of employees being the primary criterion for determining the size of construction firms. Despite this challenge, SMEs play a significant role as economic drivers, acting as employment providers and job creators with the flexibility to foster new developments. In fact, they contribute a greater proportion of output in many countries around the world. SMEs account for nearly two-thirds of global employment and more than 50% of GDP in numerous nations (Madhavika et al., 2024).

SMEs are important to the economic development in both global and local contexts in several ways. SMEs are where large companies originate, making them the breeding grounds for larger organizations (Central Bank of Sri Lanka, 2021). Moreover, they are important as employment providers, which assist in improving the social status of people by reducing poverty. It is stated that SMEs cover 70% of employment worldwide ("The Power of small", 2019). According to World Bank estimates, by 2030, there will be a need for 600 million jobs for the growing population. Considering the high population growth in developing countries, SMEs will become considerably important as an employment provider (Central Bank of Sri Lanka, 2021). The flexible nature of SMEs makes them an essential sector during different downward economic situations, such as economic crises and pandemics, as well (Rizkiya, 2024). They can absorb new technology and knowledge more easily, which makes start-ups and SMEs be used as incubators for innovations which in future could be developed into major organizations (Xinhua, 2021). In Sri Lanka, SMEs are crucial in exports as well. Even though not seen, SMEs play a crucial role in Sri Lankan exports and can contribute more if the necessary frameworks to support SMEs are developed (Sri Lanka Export Development Board, 2022).

While recognizing the importance of SMEs, it is essential to adopt good practices that can enhance their capacity and capabilities. Legal provisions for SMEs vary significantly across countries. A key aspect is the establishment of proper legislation governing SME operations, including company registration, which has proven successful in countries like Japan (Nakagawa, 2012). Japan, which recognizes SMEs as a major economic driver, has dedicated legislation supporting them (Nakagawa, 2012). In contrast, countries such as the Philippines and Singapore lack specific laws targeting SMEs (Association of Southeast Asian Nations [ASEAN], 2025). Additionally, Sri Lanka does not have a dedicated SME act, relying instead on a National Policy Framework. However, several acts, such as The Inland Revenue Act No. 24 of 2017 and The Intellectual Property Act No. 36 of 2003, address certain aspects of SMEs' operations (Diriya Sri Lanka, 2024).

Construction industry SMEs play a similar role in driving economic growth; however, the sector requires unique approaches due to its specific characteristics. Most SME legislations are generic and not tailored to the construction industry. Therefore, it is important to develop a construction-specific legal framework (Mengistu et al., 2024). In addition to legal provisions, fostering innovation within SMEs is essential (Central Bank of Sri Lanka, 2021). Creating opportunities for SMEs to network with other industry organizations will help enhance their knowledge base and compete globally with confidence (Chen & Mitra, 2022). Digital transformation plays a crucial role in the development of SMEs, with legal and financial support facilitating progress, as evidenced

by successful examples in Brazil (Patterson-Waites, 2023). Furthermore, adherence to e-commerce is vital, particularly for Sri Lanka (Gunawardene, 2017).

Given these challenges, there is a pressing need to examine the role of SMEs in both local and global contexts and explore the best practices, legal frameworks, and innovations that can be adopted to strengthen the SME sector, particularly in Sri Lanka. Therefore, it is crucial to identify how Sri Lanka can adapt successful global practices to its unique context and enhance the capacity of its SME sector, particularly in construction, to contribute more effectively to economic growth and development. Therefore, this study aims to investigate SMEs in local and global context comparatively focusing on four main areas; (1) definitions of SMEs in global and local contexts, (2) importance of SMEs in the economic development in global and local contexts, (3) legal provisions related to SME contractors in global and local contexts and (4) good practices that can be derived from global context to enhance the local SMEs. The structure of the paper is as follows: The introduction is followed by the methodology section. The findings, based on a scoping review, are then presented. The paper concludes with a summary and suggestions for future research.

2. METHODOLOGY

This study employed a scoping review to collect data, and the findings were interpreted through content analysis.

Scoping Review

A Scoping Review Methodology was utilised to systematically examine existing literature and assess the significance of best practices in SMEs, comparing global and local contexts. This approach aimed to provide a factual and relatable understanding of SME development, particularly in the context of a developing country.

Scoping reviews serve as an evidence synthesis tool, mapping the breadth of available research on a specific topic, concept, or issue within defined contexts (Pollock et al., 2024). Authors have followed nine key steps (Peters et al., 2021) and JBI (Joanna Briggs Institute) guidelines when conducting the scoping review, as illustrated in Figure 1.

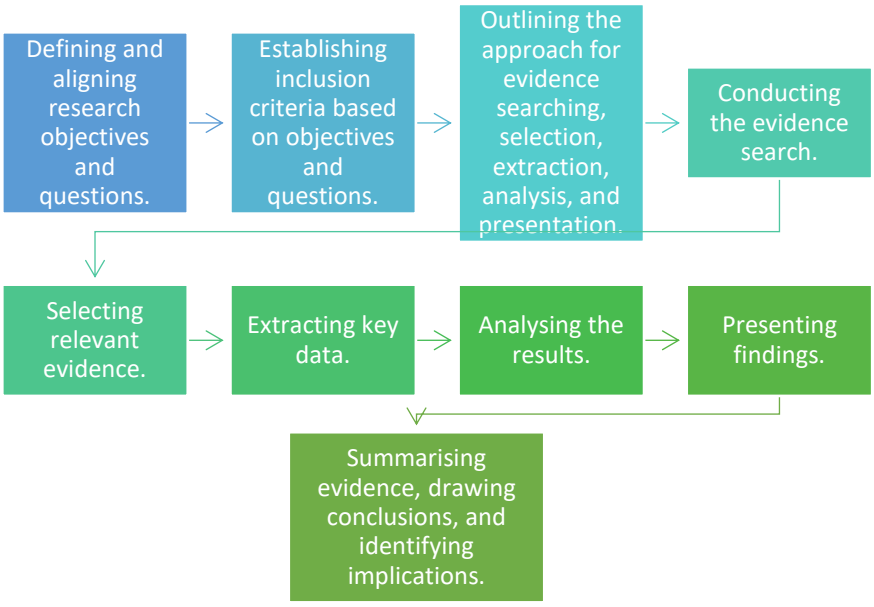

Figure 1: Steps followed when conducting the scoping review

Content Analysis

Qualitative data collected from scoping review was analysed using content analysis, a systematic method for identifying patterns, themes, and insights within textual data (Ullah & Ameen, 2018). This approach involves categorizing and coding information to uncover relationships and trends relevant to SME contractors in the construction sector. The insights generated through content analysis assisted in identifying the viability of good practices that can be adopted and effective steps to be taken.

3. FINDINGS AND ANALYSIS

3.1 DEFINITIONS OF SMES IN GLOBAL AND LOCAL CONTEXTS

Definitions of SME distinctly vary from country to country. Hence, there is no universally recognized definition (Acar et al., 2005). Acar et al. (2005) further added that the term SME has varying definitions are a result of the different phases of economic development, size and prevailing social conditions of the country. However, most of these definitions are based on criteria that refer to employment, annual turnover, size of balance sheet, assets, invested capital, sales volume and production capacity, while the most conventional reference is the number of employees (ESCAP, n.d.)

Table 1: Definitions of SMEs

Country	Sector	Currency	Criteria	Micro		Small		Medium	
				No. of Employees	*Value*	*No. of Employees*	*Value*	*No. of Employees*	*Value*
Malaysia	Manufacturing [1]	RM	Sales turnover	1-4	< 0.3 Mn	5-74	0.3 – 15 Mn	75-200	15-50 Mn
	Services and other [1]	RM	Sales turnover	1-4	< 0.3 Mn	5-29	0.3 – 15 Mn	30-75	3-20 Mn
Philippines	[1]	PHP	Total assets exclusive of land		≤ 3 Mn		3- 15 Mn		15- 100 Mn
Singapore	[1]	SGD	Sales turnover	≤ 200	≤ 100 Mn	≤ 200	≤ 100 Mn	≤ 200	≤ 100 Mn
Vietnam	Agriculture, forestry and fishing Industry and construction [1]	VND	Total revenue	1 - 10	< 3 billion & < 3 billion	11 - 100	3-50 billion & 3-20 billion	101 - 200	50-300 billion & 20-100 billion

Country	Sector	Currency	Criteria	Micro		Small		Medium	
				No. of Employees	*Value*	*No. of Employees*	*Value*	*No. of Employees*	*Value*
European countries	[2]	Euro	Turnover	< 10	≤ 2 Mn	< 50	≤ 10 Mn	< 250	≤ 50 Mn or
		Euro	Balance sheet		total ≤ € 2 Mn		total ≤ 10 Mn		≤ 43 Mn
India	Manufacturing and Service Sector Enterprises [3]	Indian Rupees	Investment in Plant and Machinery or Equipment		up to 10 Mn		up to 100 Mn		500 Mn and
		Indian Rupees	Annual Turnover		< 50 Mn		< 500 Mn		< 2500 Mn
Japan	Manufacturing and Others (including construction sector) [4]	Yen	Capital			20 or less		300 or less	300 Mn or less
	Wholesale [4]	Yen	Capital					100 or less	100 Mn or less
	Retail [4]	Yen	Capital					50 or less	50 Mn or less
	Service [4]	Yen	Capital			5 or less		100 or less	Capital 50 Mn or less
Sri Lanka	Manufacturing Sector [5]	Rupees	Annual turnover	Less than 10	less than 15 Mn	11 - 50	16 – 250 Mn	51 - 300	251 – 750 Mn
	Services Sector [5]	Rupees	Annual turnover	Less than 10	less than15 Mn	11 - 50	16 – 250 Mn	51 - 200	251 – 750 Mn

Country	Sector	Currency	Criteria	Micro		Small		Medium	
				No. of Employees	*Value*	*No. of Employees*	*Value*	*No. of Employees*	*Value*
	Construction Sector [6]	Rupees	Annual turnover				Rs. 16 - 250 Mn, CIDA grade C9 – C4		250 - 750 Mn, CIDA grade C3 – C2

[1]: (ASEAN, 2024), [2]: (European Commission, n.d.), [3]: (SME Chamber of India, n.d.), [4]: (Organization for SME and Regional Innovation, n.d.), [5]: (Ministry of Industry and Commerce, 2016), [6] :(Ranadewa, et al., 2018)

Table 1 shows a comparison of several countries' definitions of SMEs. In Southeast Asia, the definitions vary depending on the country's income level. For instance, Malaysia, an upper middle-income country with a population similar to Sri Lanka's, defines SMEs differently from the Philippines, which is a lower middle-income country. On the other hand, Singapore, a high-income and developed country, does not differentiate between micro, small, and medium enterprises (Metreau et al., 2024; Wickrmatilake, 2018). Furthermore, it can be observed that most ASEAN countries do not specifically have classified construction SMEs. However, Vietnam stands out as it provides a definition for construction SMEs alongside other industrial SMEs.

In Europe, where most countries are high-income nations (Metreau et al., 2024), the definition of SMEs is typically based on three key criteria (European Commission, n.d.). In India, a fast-developing country, SMEs are defined according to a composite criterion that includes investment in plant and machinery/equipment and annual turnover (SME Chamber of India, n.d.). The definition for construction industry SMEs in India aligns with this general SME definition, as stipulated in the MSMED Act 2006 and the Industries Development and Regulations Act 1951. Similarly, Japan, another high-income country (Metreau et al., 2024), defines SMEs in accordance with the criteria depicted in Table 1 (Organization for SME and Regional Innovation, n.d.).

In Sri Lanka, SMEs are generally defined by the number of employees and annual turnover, as outlined in the National Policy Framework for SME Development by the Ministry of Industry and Commerce (Ministry of Industry and Commerce, 2016). For construction SMEs, the definition is proposed to be based on annual turnover and CIDA grading, as provided by the Ceylon Institute of Construction Development (Ranadewa et al., 2018). However, it is important to note that there is no universally recognized classification system for construction industry SMEs.

3.2 IMPORTANCE OF SMES IN ECONOMIC DEVELOPMENT IN GLOBAL AND LOCAL CONTEXTS

In developing economies, construction SMEs play a crucial role in job creation and poverty reduction (Usman & Alaezi, 2016). Consequently, acknowledging the economic significance of SMEs within the construction sector is essential (Ranadewa et al., 2015). The following section provides a summary of the contribution of SMEs to economic development in both global and local contexts.

3.2.1 A Breeding Ground for large Organisations

Most of the present business giants have once been initiated as small businesses. Large businesses are more productive, have better access to finance, the capacity to invest in bigger projects and the ability to facilitate research and development, while MSMEs play the role as the breeding ground for the large businesses. A successful economy should have a healthy mix of both large and small businesses. MSMEs contribute to influencing the general public's entrepreneurship, which helps the growth of the economy by enhancing human capital (Central Bank of Sri Lanka, 2021).

3.2.2 Employment and Job Creation

SMEs contribute to approximately 70% of global employment, serving as key drivers of job creation, particularly in developing economies ("The Power of Small", 2019). In the construction sector, SMEs play an essential role in employing both skilled and unskilled labourers, directly impacting income levels and poverty reduction (Anaman & Osei-Amponsah, 2007). The Employment-Intensive Investment Program (EIIP) highlights that 220 million people worldwide are employed due to the construction industry ("The Power of small", 2019). However, challenges such as job continuity and workforce retention persist, especially in developing countries where SMEs operate under uncertain and volatile market conditions (Ranadewa et al., 2018).

3.2.3 Innovation

SMEs are recognised as hubs for innovation, contributing to economic development by introducing new products, services, and technological advancements (Amoah et al., 2022). Their flexible structure enables them to adapt quickly to market demands and invest in creative solutions. Countries such as China have actively supported SME-led innovation through initiatives like the incubation of "little giants" in high-tech industries (Xinhua, 2021). Similarly, European SMEs have played a significant role in patent development, particularly in fields like biotechnology (Bayraktar & Algan, 2019). Sri Lankan SMEs also contribute to innovation, offering unique solutions that enhance competition and drive industry advancements (Rizkiya, 2024).

3.2.4 Fulfilment of Corporate Social Responsibilities

Amoah et al. (2022) discussed the importance of SMEs, including employment, job creation, and innovation, which have ultimately contributed to Africa's economic growth. Additionally, Sri Lanka is a country with a similar developing economy to Ghana in Africa, in which SMEs have given their contribution to the fulfilment of social responsibilities and economic growth as mentioned in the table above (Central Bank of Sri Lanka, 2021).

3.2.5 Exports

According to what is mentioned in the table above SMEs represent a hopeful market for goods and services exports in Sri Lanka (Sri Lanka Export Development Board, 2022). It is said that export of construction services, which could be categorized as construction work, consultancy in construction work and project development work, could become the panacea for the laid-up construction industry of the country as well as the Sri Lankan Economy (Wijeratne, 2023).

3.3 LEGAL PROVISIONS RELATED TO SME CONTRACTORS IN GLOBAL AND LOCAL CONTEXTS

SMEs, or small enterprises, play a crucial role in engaging with communities and fostering innovation in the development of products and services for consumers within a market economy. As economies undergo digital transformation, SMEs act as catalysts for change, driving the shift towards a new market structure. Governments must ensure that laws, regulations, and policies support the establishment and growth of SMEs. Consequently, many countries have implemented legislation and strategies designed to promote the development of SMEs.

In Sri Lanka, there is no exclusive legal provision for SMEs, but there is the National Policy Framework for SME development, which outlines the vision, mission and strategies for promoting and supporting the MSME sector (Diriya Sri Lanka, 2024). Additionally, there are certain other acts which address different aspects of SMEs as mentioned above. Figure 2 presents an overview of the various legislative frameworks and legal provisions that have been adopted by countries globally to govern and support SMEs.

3.4 GOOD PRACTICES THAT CAN BE DERIVED FROM GLOBAL CONTEXTS TO ENHANCE THE LOCAL SMES

Enhancing the capabilities and competitiveness of Sri Lankan SMEs necessitates a comprehensive approach that incorporates successful strategies and best practices from a variety of global contexts (Gamba, 2019). Given the substantial role of SMEs in fostering economic development, particularly in developing nations, it is essential to address the challenges they encounter and bolster their ability to compete in the global market. (Issau et al., 2022). In order to overcome these obstacles and fully realise the potential of Sri Lankan SMEs, policymakers and business leaders can benefit from the insights gained from international experiences, adapting proven models to meet the specific needs and context of the Sri Lankan economy (Gamba, 2019; Ranadewa et al., 2018).

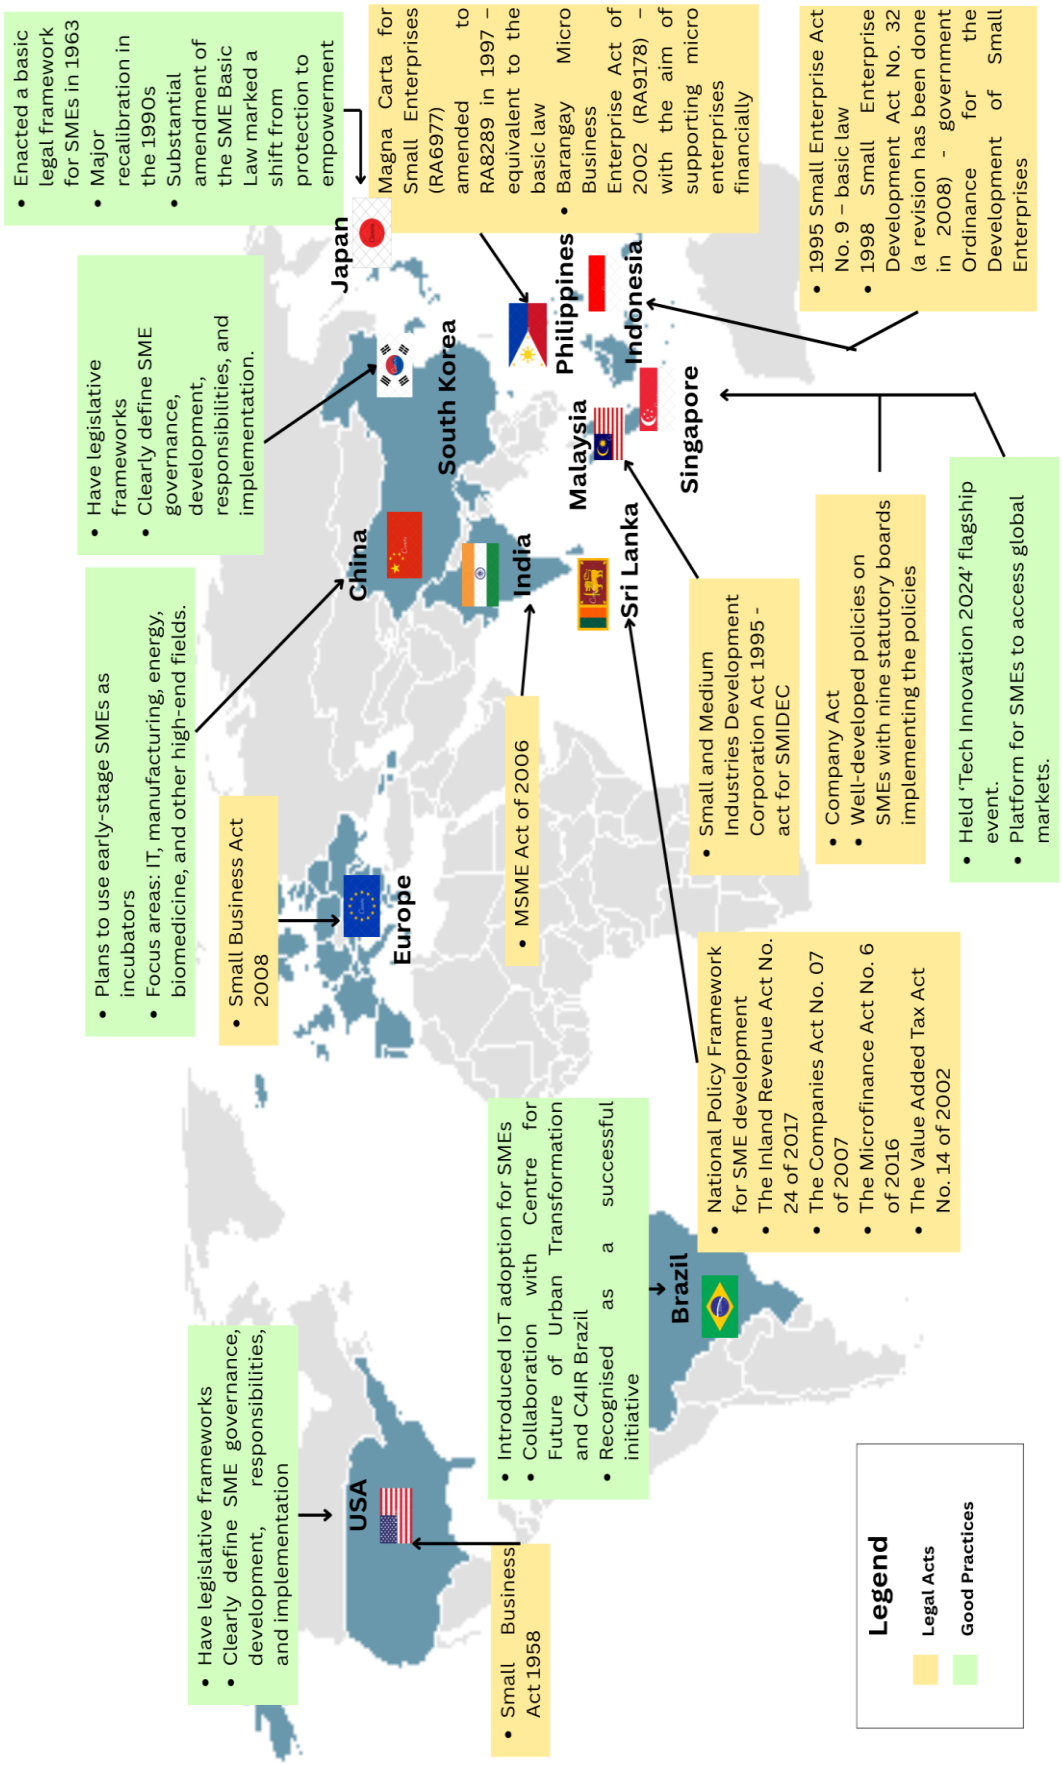

Figure 2: Legal provisions related to SME contractors in global contexts & good practices that can be derived from global contexts to enhance the local SMEs

Figure 2 provides a summary of the best practices that can be adopted from other countries to strengthen Sri Lankan SMEs.

3.4.1 Establishment of Targeted Legal Provisions

Japan and South Korea provide strong examples of SME-focused legislative frameworks, ensuring clarity in governance, development, and policy implementation (Nakagawa, 2012; Knowledge and Research, 2020). The recalibration of Japan's SME Basic Law in the 1990s transformed SMEs into drivers of economic growth rather than passive recipients of protection. Similarly, Sri Lanka requires a dedicated legal framework for SMEs, particularly in the construction sector, to address challenges such as payment paralysis and contract enforcement issues (Rajapakshe et al., 2021; Kaggiah, 2022). Implementing clear legal provisions would create a more supportive business environment and facilitate sustainable SME growth.

3.4.2 Digital Transformation and E-Commerce

The adoption of digital technologies is crucial for enhancing SME productivity and market reach (Patterson-Waites, 2023). Brazil's successful integration of IoT solutions for SMEs demonstrates how digitalisation can significantly improve operational efficiency and return on investment (Aguilar & Salihudin, 2024). However, Sri Lankan SMEs face challenges such as high transaction fees for online payment systems and limited access to digital resources (Gunawardene, 2017). Encouraging affordable digital payment solutions and providing digital literacy training can enhance the participation of SMEs in e-commerce and global trade.

3.4.3 Empowering SMEs to Initiate and Develop Innovations

China has strategically positioned SMEs as incubators for emerging technologies in manufacturing, energy, and biotechnology, integrating them into broader industrial and supply chains (Xinhua, 2021). In Sri Lanka, fostering SME-driven innovation is critical for economic progress. For the construction industry, innovation can be influenced by client demand, procurement arrangements, and collaborative project environments (Hardie & Newell, 2011). Establishing research partnerships and providing financial support for innovation-driven SMEs will strengthen their role in sustainable development.

3.4.4 Improving Linkages to Compete Internationally

Singapore's 'TechInnovation 2024' event facilitates strategic matchmaking among potential business partners where innovators, technology providers, and industry leaders are present. The main goal of IPI, which is the organizer of this event, is to improve the linkage of Singaporean companies with international partners (Asia Research News, 2024). Industry networks heavily impact the innovative capacity of construction industry SMEs as well. Knowledge sharing and joint problem solving through collaboration could enhance each other's capacity. However, there should be opportunities, such as forums by professional associations and research associations in order to provide a proper industry network (Hardie & Newell, 2011).

A thorough and context-sensitive approach is necessary to improve the performance, resilience, and long-term viability of Sri Lankan SMEs, especially in the construction industry, by taking inspiration from these global best practices. First, the creation of a strong and well-defined legal framework based on successful programs in the US, South Korea, and Japan would enhance contract enforcement, create a stable policy

environment, and address systemic problems like poor dispute resolution and late payments. Having such a legal basis is essential for boosting investor trust and promoting SME involvement in official procurement processes, especially for public infrastructure projects. Additionally, SMEs can greatly improve their operational efficiency and market access by adopting digital transformation through the creation of inclusive payment systems, e-commerce platforms, and low-cost digital infrastructure. Smoother transitions to digital operations can be facilitated by strategic relationships with local financial institutions, digital innovation clusters, and international technology providers. Additionally, incorporating digital literacy into national SME development plans will guarantee fair access and lessen the digital divide between urban and rural areas.

In addition, it is critical to cultivate an innovative culture. SME participation in high-value industries can be accelerated via government-led innovation subsidies, tax breaks, and assistance for incubators and accelerators. SMEs in the construction sector might be urged to create digital project management tools, modular construction techniques, and sustainable technology. Enhancing businesses' ability to absorb innovation through upskilling initiatives and promoting knowledge transfer from academic and research institutions are also necessary for integrating innovation into the SME ecosystem. Increasing international connections will help Sri Lankan SMEs better integrate into global value chains and gain knowledge of sustainability standards and global market demands. Targeted networking gatherings, innovation expos, bilateral trade missions, and involvement in regional SME forums like ASEAN SME initiatives can all help achieve this. Additionally, creating cross-border research partnerships and exchange initiatives will support SMEs in maintaining their agility in a rapidly changing and competitive global marketplace. Lastly, it is crucial that these approaches be applied as part of a coordinated, multi-stakeholder approach that involves academic institutions, industrial associations, the private sector, the government, and international development partners. In addition to increasing the productivity and competitiveness of Sri Lankan SMEs, adjusting these techniques to the local environment while maintaining alignment with international standards will also make a substantial contribution to employment creation, national economic growth, and sustainable development. One of the main pillars of Sri Lanka's shift to a more innovative and inclusive economy will be a robust and cohesive SME sector.

4. CONCLUSIONS AND RECOMMENDATIONS

This study aimed to investigate SMEs in both local and global contexts, highlighting their critical role in driving economic growth, innovation, and employment. Although SMEs are widely recognised across nations, a standardised definition remains absent. Countries vary in classification criteria Singapore maintains a broad definition, while Japan and Malaysia apply sector-specific distinctions. Notably, construction SMEs often receive insufficient attention despite their unique operational challenges. In the Sri Lankan context, the lack of a dedicated legal framework for construction SMEs has contributed to persistent issues such as payment delays, limited access to finance, and weak institutional support. Insights drawn from international best practices underline the importance of establishing clear legal and policy structures tailored to the sector’s needs. Global examples also illustrate how digitalisation, e-commerce, innovation support, and international linkages can significantly enhance SME resilience and competitiveness.

To strengthen SME development in Sri Lanka, the introduction of a formal classification system for construction SMEs and the implementation of a targeted legal framework are essential. Complementary measures, including financial incentives, technology adoption, and innovation partnerships, will help bridge gaps between SMEs and larger enterprises. Encouraging global collaboration and knowledge exchange can further position Sri Lankan SMEs to compete in international markets. Theoretically, this study contributes by comparing SME structures across contexts and identifying key lessons for policy development. However, it is limited in its exploration of practical mitigation strategies tailored to construction SMEs. Future research should focus on contextualising international practices and developing actionable implementation plans to address specific local challenges and foster long-term SME growth.

A STUDY ASSESSING THE APPLICATION OF ARTIFICIAL NEURAL NETWORK FOR PRELIMINARY ESTIMATION IN SRI LANKAN BUILDING PROJECTS

U.P. Wijerathne[1], Udayangani Kulatunga[2] and M.L.S.S. Fernando[3]

ABSTRACT

Preliminary estimations are prepared at the early stages of every construction project to determine the project's financial feasibility. The Artificial Neural Network (ANN) method is a machine learning method that could also be utilised in preliminary estimation for forecasting and predicting the cost with higher accuracy at a very early project stage. A mixed research approach was used for this research. In the first stage, an ANN model with 11 input attributes was developed, with an obtained accuracy of 89.56% in the validation process. In the second stage, the suitability and applicability of the ANN method for preliminary estimation within the Sri Lankan context were investigated through 10 semi-structured interviews. The frequent use of traditional methods for preliminary estimation practice is widespread. Furthermore, the preferred accuracy is more than 80% in the context. The increased accuracy, time efficiency and usability of the ANN model emphasise the suitability of ANN in the construction industry. However, the insufficiency of the databases within the firms, the lack of programming knowledge, and people's reluctance to change were identified as challenges. Conversely, initiating a centralised database system within the context, outsourcing the resource requirement to develop the ANN model, and reducing the knowledge gap in the industry regarding modern methods were identified as remedies. Adding location, price fluctuation, and risk uncertainty as input attributes are suggested improvements and modifications for the ANN model, which is the first model with almost 90% accuracy.

Keywords: *Artificial Neural Network (ANN); Cost Estimation Model; Computer-based Estimation; Preliminary Estimation.*

1. INTRODUCTION

Innovative thinking drove society to a modern era where basic human needs and wants are sophisticated (Moses, 2022). Modern civilisation demands more complex, reliable, and aesthetically pleasing buildings and infrastructure to fulfil basic human needs and wants (Ubayi et al., 2024). Preliminary cost estimates are prepared to counsel on the feasibility and profitability of the project. Past project data is used to prepare preliminary estimates with necessary adjustments (Elhegazy et al., 2022). Several methods are

[1] Quantity Surveyor, Absal Paul Contracting, Saudi Arabia, umeshpasindu5@gmail.com
[2] Professor, Department of Building Economics, University of Moratuwa, Sri Lanka, ukulatunga@uom.lk
[3] Research Scholar, Department of Building Economics, University of Moratuwa, Sri Lanka, shamalfernando96@gmail.com

followed in the industry for early-stage preliminary estimation of projects, such as the gross floor area, functional unit method, cube method, and story enclosure method. These methods are usually quicker to perform but less accurate in most scenarios due to insufficient and unavailability of project information. Meharie et al. (2019) note that, even though there are methods to increase the reliability of conventional methods, the accuracy highly depends on the indices used. It emphasises the requirement and the importance of advanced cost forecasting and estimation methods suited for the current practice in the construction industry.

According to Abiodun et al. (2018), Elmousalami (2019) and Doroshenko (2020) Artificial Neural Network (ANN) could be used as a deep learning method for preliminary estimation in construction projects to overcome the drawbacks of the conventional estimating methods. Further, Hakami and Hassan (2019) mention that this method showed high effectiveness and accuracy with less than 1% error in the preliminary estimation of Yemen Projects. Supporting that, Elmousalami (2019), Kim et al. (2005), and Mohamed (2021) explain that the ANN-based preliminary estimation models have obtained a higher accuracy than conventional methods. Moreover, Hakami and Hassan (2019) and Kim et al. (2005) mentioned that ANN models have a higher accuracy when compared to regression analysis and support vector machine techniques, which have been used with project historical data for preliminary cost estimating. ANN models can be configured to have more accurate results with fewer inputs (Shehatto, 2013). Furthermore, the effects of seasonal changes and trends could be identified by an ANN model, which is more beneficial for increasing the accuracy of the estimate (Karaca et al., 2020; Sanni-Anibire et al., 2021; Tabtabai et al., 1999).

According to Akinradewo et al. (2020) and Jassim et al. (2025), industrial practice for preliminary estimation in Sri Lanka is to use conventional methods. In most scenarios, it causes a less accurate estimate and consumes a significant amount of time to prepare. Gupta & Debnath (2022) declared that existing estimation software in the international market is incompatible with the Sri Lankan context due to limited usage policies and availability. However, ANN-based preliminary estimation has provided promising results in the global context (Al-Tawal et al., 2021; Matel et al., 2022). Therefore, adopting the ANN method for preliminary estimation can be recognised as suitable for the Sri Lankan context. Further, it will assist the parties involved in the project to determine future project decisions more accurately with less information available. The study aims to investigate the applicability of artificial neural network-based methods to enhance the preliminary estimation in Sri Lankan building construction projects. An ANN model is developed, and necessary improvements and modifications relevant to the cost attributes are suggested to enhance the practical implementation of the ANN method within Sri Lanka.

2. LITERATURE REVIEW

2.1 PRELIMINARY COST ESTIMATION FOR BUILDING PROJECTS

Preliminary cost estimates should provide a credible and accurate prediction of the cost at an early stage of a construction project (Kim et al., 2005; Phaobunjong, 2002; Sanni-Anibire et al., 2021; Seeley, 1996; Shehatto, 2013). Gould (2005) explains the preliminary cost estimation as an appraisal, opinion, or approximation of the cost done before the actual construction. Further, Ofori-Boadu (2015) explains preliminary cost estimation as one of the cost estimates prepared in the initial step of developing the budget

for a construction project. Therefore, the task becomes more challenging, especially when a higher accuracy level is required for the estimate at the initial stage of the project (Shehatto, 2013). Holm et al. (2005) describe that preliminary estimations are required to select alternative investment options and design options to determine the funding requirements, conduct feasibility studies, and present bids and tenders. Furthermore, Cheung et al. (2012) note that the employer's requirements for the project must be assessed when preparing a preliminary estimate to perform a reliable estimate based on appropriate data.

According to Phaobunjong (2002) and Oberlender (2000), a specific format or industrial standard is not defined for preparing the preliminary estimate. The required accuracy level is determined according to the stage of the project (Gunaydin & Doğan, 2004).

2.2 ARTIFICIAL NEURAL NETWORK (ANN) FOR PRELIMINARY ESTIMATION

An ANN is a computing technique in computational intelligence that can be used for information processing (Gupta & Debnath, 2022; Kukreja et al., 2016; Rojas, 1996). ANN is inspired by the ideology of the human brain neurons. ANN was developed to easily incorporate human intelligence into computers to perform complicated tasks (Abiodun et al., 2018; Goel et al., 2023). Abiodun et al. (2018) describe that ANN models are compatible with mathematically expressing a real-world phenomenon since an ANN model is a simplified mechanism of brain function. System control, pattern recognition, forecasting, and detection are the main areas where the application of ANN is mainly identified (Kukreja et al., 2016). Matel et al. (2022) stated that ANN can be used in parametric cost estimation as an alternative to statistical methods. Moreover, the same article noted that using ANN models in preliminary estimation is more straightforward than using other evolving methods in computational intelligence.

Elmousalami (2019) was able to represent the use of simulation modelling methods for preliminary estimating in building construction projects by considering 47 studies. The use of ANN and hybrid models was emphasised in the study.

Studies conducted by Arafa and Alqedra (2011), Bayram et al. (2015), Bode (2000), Cheng et al. (2013), Elmousalami (2019), El-Sawah and Moselhi (2014), Emsley et al. (2002), Gunaydin and Doğan (2004), Hakami and Hassan (2019), Kim et al. (2005), Pesko et al. (2013), Petroutsatou et al. (2012), Shehatto (2013) and Wilmot and Mei (2005) signify the applicability of ANN method for preliminary estimation process in the construction industry which results to acquire a higher accuracy than traditional methods.

2.3 IDENTIFYING INPUT VARIABLES FOR THE ANN-BASED PRELIMINARY ESTIMATION MODEL

Identification of the most significant cost parameters of the building is vital when developing the ANN model. The cost relationship between the input variable and the output must be substantial to have more dynamic output from the ANN model and to improve the accuracy with reduced redundancy and noisiness (Arafa & Alqedra, 2011; Elmousalami, 2019; Gunaydin & Doğan, 2004; Shehatto, 2013). Further, Hakami and Hassan (2019) denote that the input variables of the ANN model should expose the client's requirements to increase the model's reliability. Table 1 represents key building

parameters that could be used as input variables for the ANN model, as identified by various authors.

Table 1: Building parameters used as input variables for ANN models in previous research studies

Building Parameter	References
Floor area	(Arafa & Alqedra, 2011; Chandraratne et al., 2019; Geekiyanage & Ramachandra, 2019; Gunaydin & Doğan, 2004; Kim et al., 2005; Shehatto, 2013; Sonmez, 2011; Wang et al., 2012)
Type of the foundation	(Arafa & Alqedra, 2011; Chandraratne et al., 2019; Gunaydin & Doğan, 2004; Kim et al., 2005; Shehatto, 2013; Wang et al., 2012)
Number of floors	(Arafa & Alqedra, 2011; Chandraratne et al., 2019; Geekiyanage & Ramachandra, 2019; Gunaydin & Doğan, 2004; Hakami & Hassan, 2019; Kim et al., 2005; Shehatto, 2013; Sonmez, 2011; Wang et al., 2012)
Number of elevators	(Arafa & Alqedra, 2011; Shehatto, 2013; Sonmez, 2011; Wang et al., 2012)
Building height	(Chandraratne et al., 2019; Geekiyanage & Ramachandra, 2019)
Building type	(Chandraratne et al., 2019; Hakami & Hassan, 2019; Shehatto, 2013)
Project location	(Chandraratne et al., 2019; Gunaydin & Doğan, 2004; Hakami & Hassan, 2019)
Project duration	(Chandraratne et al., 2019)
Type of HVAC	(Hakami & Hassan, 2019; Shehatto, 2013)
Type of electricity	(Shehatto, 2013)
Mechanical services type	(Shehatto, 2013)
Type of external finish	(Hakami & Hassan, 2019; Shehatto, 2013; Sonmez, 2011; Wang et al., 2012)

According to Table 1, floor area, type of foundation and number of floors are significant building parameters for the ANN model. Moreover, the studies conducted by Chandraratne et al. (2019) and Geekiyanage and Ramachandra (2019) additionally, emphasise the significance of building parameters, namely building height, building type, location and project duration, concerning the Sri Lankan context.

3. MATERIAL AND METHODS

This research intends to investigate the suitability and applicability of ANN-based preliminary estimation in Sri Lanka through design science research methodology. Specifically, the suitability and relevance of ANN within the Sri Lankan context were evaluated using a qualitative method. The ANN model development and validation were approached using a quantitative method since it should be performed using numerical figures generated from performance measures as identified in the literature review. This research consisted of two main stages, and the required activities and the sequences of activities for this research study at each stage were identified in Figure 1.

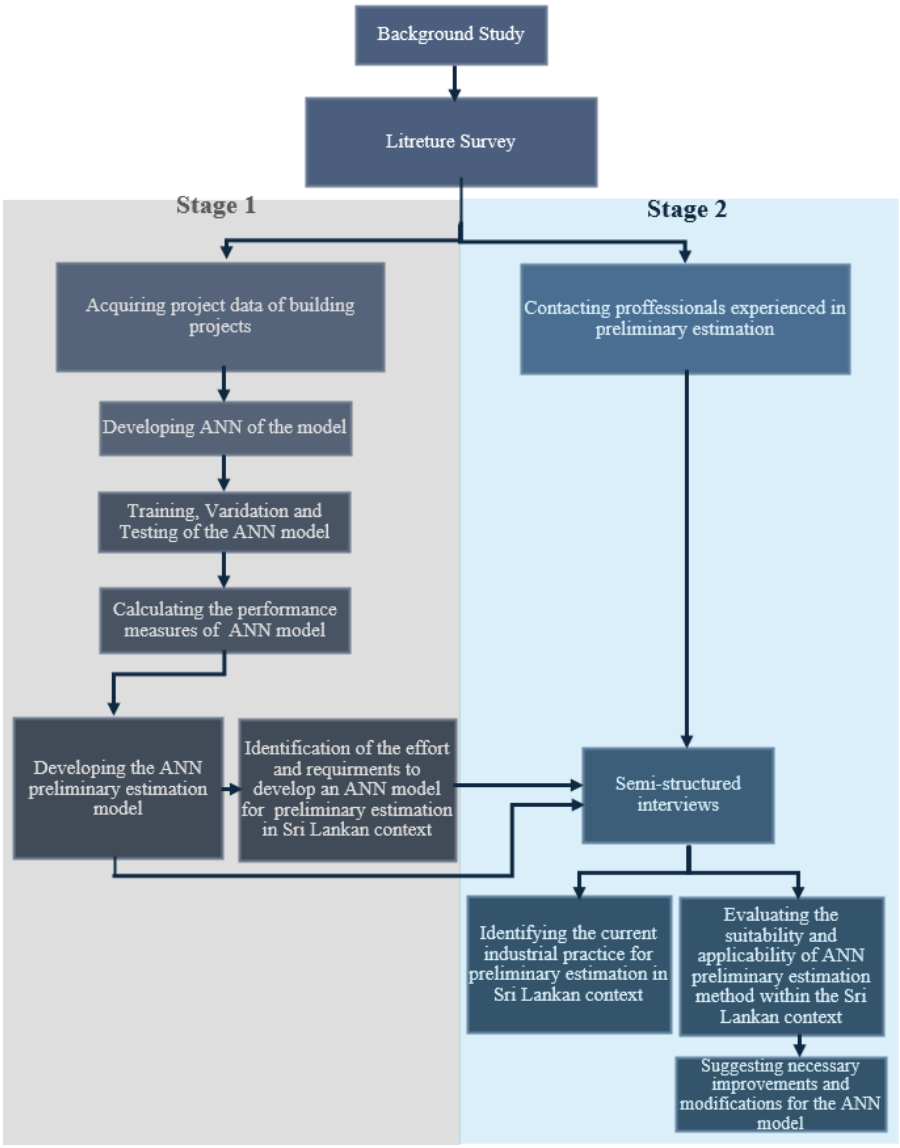

Figure 1: Research process

Fellows and Liu (2015) explain that expert interviews are more beneficial for effective data collection, as they gather data for a relevant matter from someone experienced. Therefore, 10 semi-structured interviews with the building construction sector (Quantity surveyors, Cost consultants, and Project managers) were conducted, since this study should elaborate on the suitability and applicability of ANN for preliminary estimation, which would be a new subject matter for the interviewees. Since the number of experts is unknown in this study area sample size is determined based on the saturation of the information. Snowball sampling is adopted for this study to select suitable experts for the study data collection. Accordingly, data were collected from 10 experts in the building construction sector.

The quantitative analysis report comprises performance measures of the developed ANN preliminary estimation model. The measures can be identified during the ANN model validation process and used for the performance evaluation of the ANN model. An efficient analysis was conducted by adopting qualitative data analysis. Therefore, content

analysis is preferred in this research to perform Stage 2 of this research. As the preliminary estimation model development platform Google Colaboratory platform is used, and its selection has been justified in Subtopic 4.1.3.

4. RESULTS

4.1 STAGE 1: ANN ESTIMATION MODEL DEVELOPMENT

4.1.1 Identification of Input Attributes and Encoding

In this study, categorisation and data encoding were carried out according to the availability of the dataset. The qualitative attributes of the buildings were encoded, and the quantitative attributes were inserted as numerical values. The relation of each input attribute to the cost was identified through Figure 2, generated using Python coding libraries in the Google Colaboratory platform, where the calculation is processed statistically within the model.

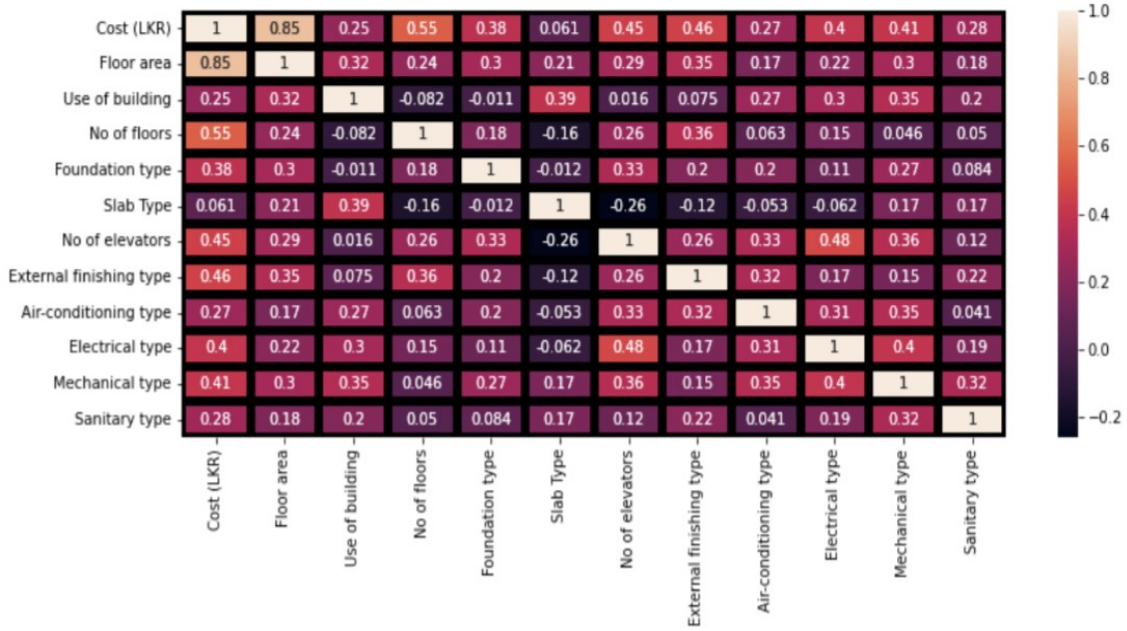

Figure 2: Correlation of cost to each input attribute

Figure 2 shows that the floor area is the most significant input attribute to the cost, and the slab type is the least affecting input attribute. Therefore, it can be stated that various input attributes can be considered when preparing the database as per the ANN model developer's desire. The correlation figure could be generated from Google Colaboratory to identify the model's most significant and suitable input attributes. Then the ANN model was developed using a database related to the UAE with 169 building projects.

4.1.2 Evaluation of the Data Distribution of the Database

Evaluation of the data distribution is mandatory to develop a reliable ANN model. The review of the data distribution was conducted through the Google Colaboratory platform. The data is preferred to be generally distributed within the expected range. Therefore, the data distribution of the most significant input attributes identified in Figure 2, and the model output attribute must be studied before the model development. This data set evaluation would be more beneficial in generating a model with higher accuracy. Figure

3 displays the data distribution of the most cost-significant input attribute (floor area) and the output attribute (building cost) specified in this ANN model.

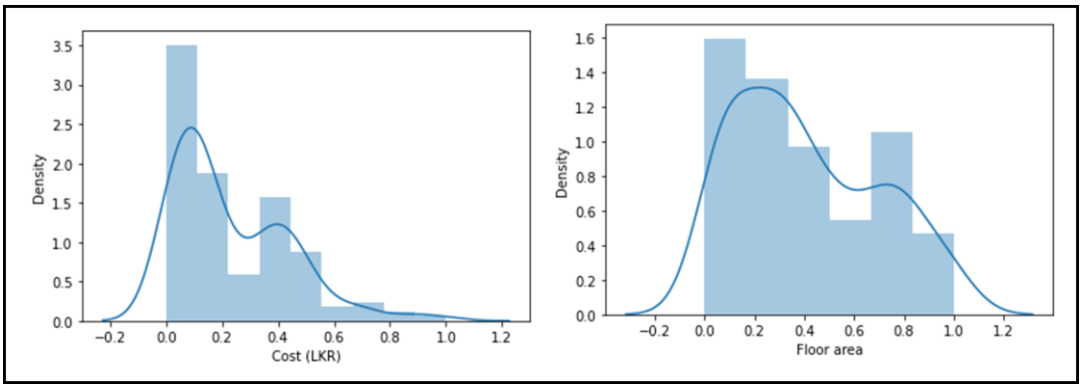

Figure 3: Data distribution of building cost and the floor area in the dataset

According to Figure 3, the selected dataset represents a bimodal distribution of data rather than a normal distribution. It emphasised the need for more mid-range cost data within the chosen dataset so that the ANN model could be more accurate in estimation.

4.1.3 Developing the ANN Preliminary Estimation Model

Three ANN preliminary estimation models were developed using the Google Colaboratory platform, MATLAB Software and Neural Designer Software. The Google Colaboratory platform enabled the development of models from scratch with Python coding online. At the same time, MATLAB and Neural Designer software were capable of developing ANN models without coding knowledge.

The models' ANN architecture, training, and testing processes were substantially similar, although the sequential model is significantly different from the Google Colaboratory model. The Google Colaboratory model is highly customisable compared to the MATLAB and Neural Designer models. (Ray et al., 2021; Sukhdeve & Sukhdeve, 2023). The architecture of the ANN model can be changed as the developer desires. The ANN models developed using MATLAB and neural designer software took less time to create, but a cost was incurred for the purchase of the software. In contrast, the Google Collaboratory platform was available free of cost. When considering the performance measures of each model, the correlation and validation performance of the Google Colaboratory and MATLAB models are shown in Figure 4.

Both models were able to achieve a correlation of more than 0.96 and were able to obtain a validation performance within the respective range of epochs. The ANN model developed in Neural Designer software validated a lower accuracy than the other two ANN models.

4.1.4 Validation of the ANN Models

The ANN model was developed using three methods to identify the resource requirement critically. The best ANN model was the Google Colaboratory model, developed using Python. It showed an accuracy of 89.56% and was prioritised for presentation in the interviews. The higher accuracy of the ANN model supports the sound examination with a minimised margin for errors. It benefits the contractor to obtain higher profits and gain customer satisfaction and trust. Meanwhile, accurate estimation avoids the requirements of price adjustments for the client, creating price certainty in the projects.

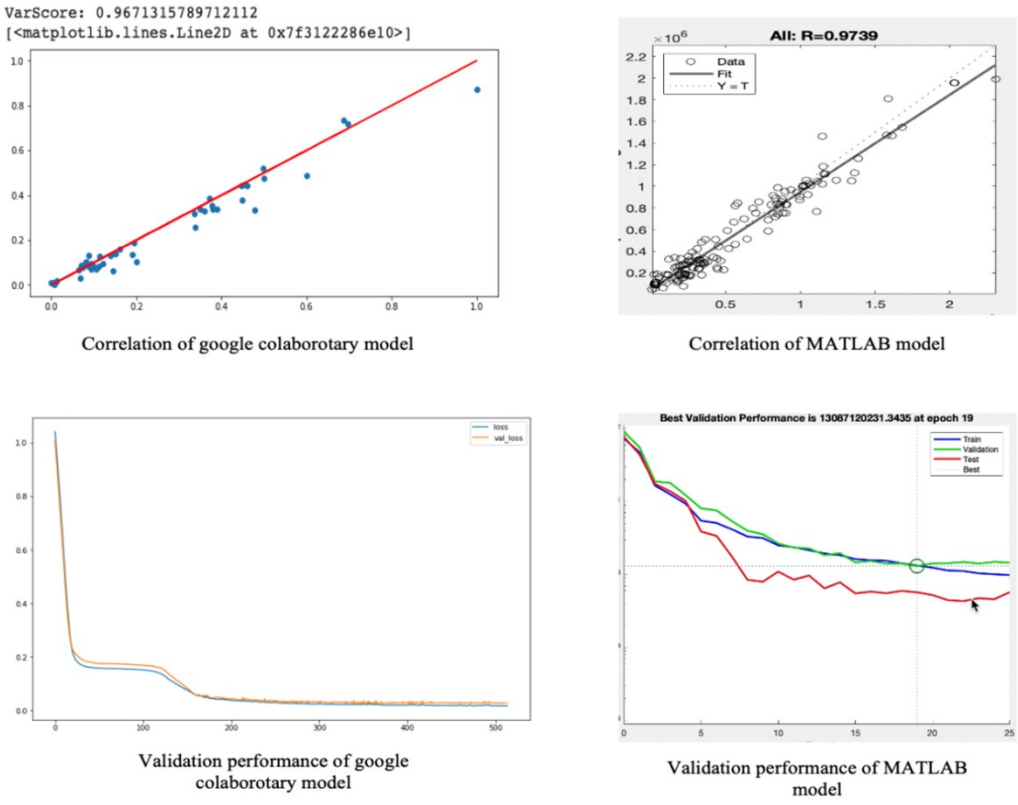

Figure 4: The correlation and validation performance of ANN models

4.2 STAGE 2: SEMI-STRUCTURED INTERVIEWS

4.2.1 SWOT Analysis of ANN Model Applicability within a Firm

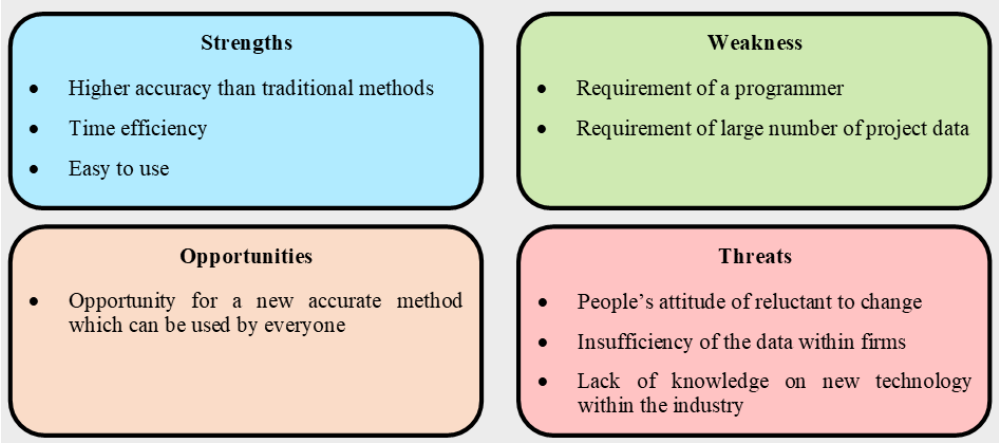

Figure 5: SWOT analysis of ANN model applicability within a firm

Figure 5 demonstrates the SWOT analysis by referring to the interviewees' responses regarding using an ANN model for preliminary estimation within the Sri Lankan context.

4.2.2 Driving and Resisting Factors for ANN-based Preliminary Estimation Model

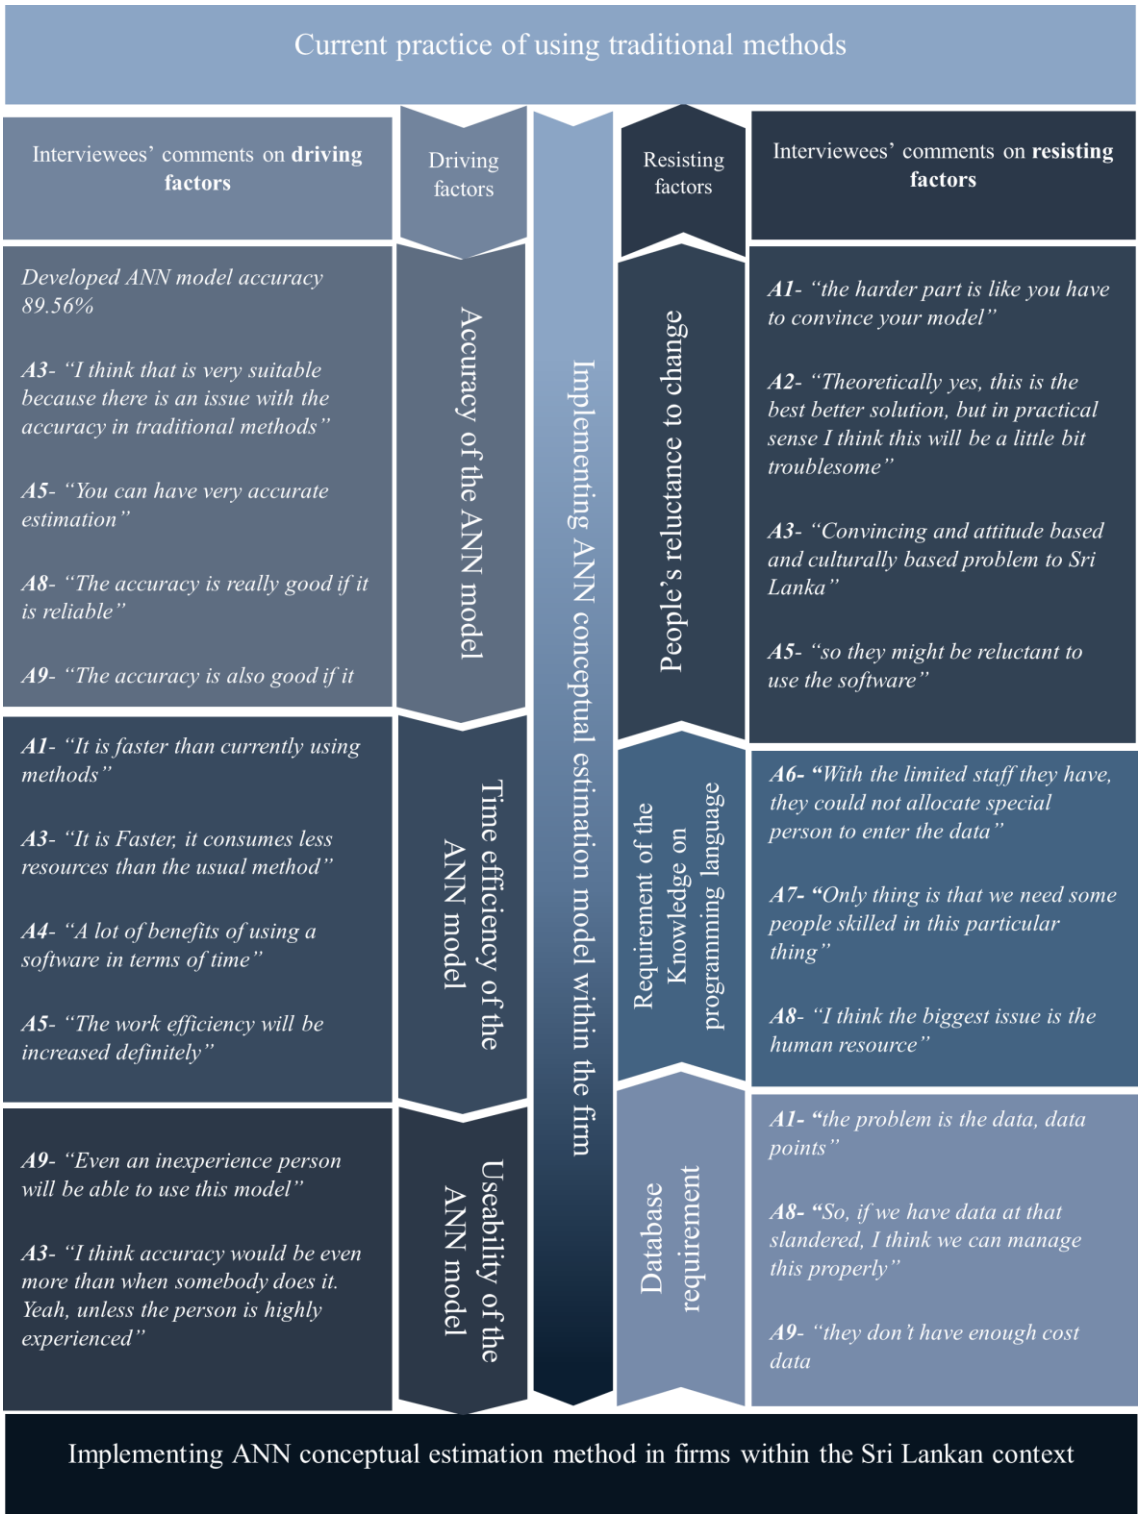

Figure 6: Identified driving and resisting factors in ANN model applicability

Further, according to the interviewees' responses, Figure 6 was developed to identify the driving and resisting factors for applying the ANN-based preliminary estimation model in the Sri Lankan context.

The interviewees strongly identified the time efficiency and the accuracy of the ANN preliminary estimation model, which will be more advantageous in overcoming the issues of the existing industrial practice of using traditional methods for preliminary estimation.

4.2.3 Suggested Improvements and Modifications for the ANN Model to Optimise its Use in the Sri Lankan Context

According to the research objectives, necessary improvements and modifications for the ANN model have been suggested to optimise the practical application within the industry. Interviewees A1, A4, A7, and A8 have identified that the model should be competent in estimating the different site conditions and settings, and interviewees A9 and A10 identified it as considering the location factor for estimation. Further, the interviewees A2, A6, A7, A9, and A10 emphasised that the model should be capable of being used for a preliminary analysis of the price fluctuations in the industry. Specifically, the interviewees A2, A6 and A7 questioned how the use of CIDA indices could be performed when using the model.

The next improvement identified was having a user interface for the model, where the efficient and effective interaction between the model and the user can be improved. The interviewees A1, A3, A5 and A6 denoted the need for a user interface for the model.

As a further improvement, the interviewees A4, A5, A6 and A7 denoted the importance of the model and whether it can be developed to prepare elemental cost planning. Furthermore, interviewees noted that the model would be more useful since the firms are primarily concerned about the elemental cost plan rather than the preliminary estimate.

Concerning the expected modifications, being location-specific, adjustments to price fluctuations and identifying the risk and uncertainty were identified by the interviewees as recommended modifications. Further, improvements in developing a user interface and compatibility with the model in elemental cost planning were emphasised.

5. DISCUSSION

The ANN model developed by Chandraratne et al. (2019), Dissanayake et al. (2015) and Geekiyanage and Ramachandra (2019) was developed using supplementary software, which was made to establish ANN models. Therefore, customizability is low compared to developing an ANN by using Python coding. There should be knowledge regarding ANN to develop an ANN model within a firm. Further, the ANN model developed for this research is a solitary model developed using only ANN, and it was able to perform with an accuracy of 89.56%. Therefore, it can be identified that the ANN is suitable for predicting the costs of building projects at the conceptual stage, as similarly identified in the literature review.

According to the interviews, the Sri Lankan preliminary estimation process still relies on traditional methods. Chandraratne et al. (2019), Dissanayake et al. (2015), Geekiyanage and Ramachandra (2019) and Rathnayake et al. (2018) also mentioned that traditional methods are still in practice in almost all preliminary estimations. According to the interviewees, the reason for using the conventional method in the industry is the simplicity of those methods. People mostly use their experience to prepare estimates (Britto et al., 2013; Dissanayake et al., 2015; Ganeshu et al., 2015). However, traditional and non-traditional methods are being replaced globally by hybrid intelligent models (Elmousalami, 2019; Sanni-Anibire et al., 2021).

Regarding preliminary estimation within the context, it is recognised that the consultant interacts with the client to gather as much information regarding the project as possible. The assumptions are made for the deficiency of information, mostly on building specifications, duration, and price fluctuations. Further, the consultants identify the client's requirements. Bley (1990) and Phaobunjong (2002) also identified the preliminary estimation process similar to the existing practice in Sri Lanka.

With the existing practice, it will take several days to analyse the data and provide a figure to the client. However, using ANN, time consumption can be drastically reduced when providing such a figure to a client. In contrast, Arafa and Alqedra (2011), Hakami and Hassan (2019) and Kim et al. (2005) have also signified the time efficiency of the ANN-based preliminary estimation.

According to the findings, database management within the firms shows a trend to use software-based data collection methods rather than Excel. The use of ERP software could be identified as a trend within the industry, and previous studies have shown a trend to use traditional Excel for data keeping and management (Rathnayake et al., 2018).

Another aspect identified through the interviews was the expected accuracy of a preliminary estimate of more than 80%. Accordingly, ANN preliminary estimation could be identified as a solution where any person within the firm can use the model to get a figure after inserting the project data into the respective input attributes.

In terms of suitability, most interviewees identified that ANN is suitable for preliminary estimation, even though ANN is not familiar to interviewees. The time effectiveness and the increased accuracy were the main advantages identified by the interviewees. It is aligned with the existing research studies of Arafa and Alqedra (2011), Sanni-Anibire et al. (2021) and Shehatto (2013), where the higher accuracy and time efficiency of ANN models were elaborated.

Therefore, according to the findings, even though the ANN is suitable for the preliminary estimation, some challenges should be addressed and rectified. The interviewees noted that the centralised database system will be beneficial in these situations, and the professional bodies related to construction can be initiated to introduce these kinds of methods to the industry to address the issue of resistance to change among people in the industry.

Furthermore, necessary improvements and modifications have been suggested according to the responses of the interviews, which were mainly focused on having a user interface and inserting input parameters to the model regarding the location and site condition of the project, price fluctuations, risk, and uncertainty. These aspects can be inserted into the model as input attributes using the location indices, CIDA price indices and the inflation rate. Along with that, the data set should be updated accurately with each project's relative location indices, CIDA indices and the inflation rate.

Figure 7 elaborates on the cognitive map regarding the applicability of the ANN preliminary estimation model within the Sri Lankan context.

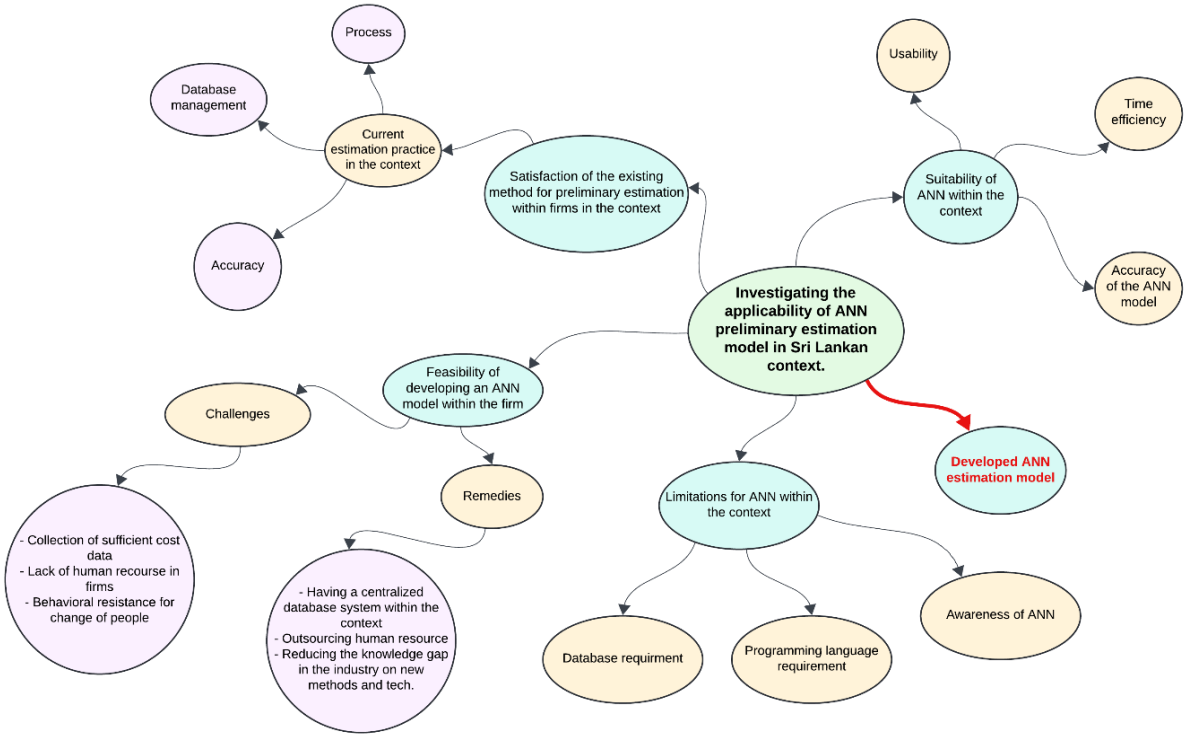

Figure 7: Cognitive map for ANN model applicability in Sri Lanka

The use of ANN for preliminary estimation is identified globally as a more accurate and easier method than the traditional method. The suitability and applicability of the ANN preliminary estimation model were critically analysed within the study. The ANN model was developed, validated, and modified according to the interviewees' responses, which were provided as improvements to the ANN model. The interviewees provided a positive impression of the applicability of ANN within the context while identifying specific challenges which can be overcome with effort within the firm.

6. CONCLUSIONS

Hybrid intelligent models are more advanced than even non-traditional methods such as MRA since hybrid intelligent models may combine several machine learning techniques, namely, evolutionary computing, ANN, SVM, CBR and fuzzy logic. Regarding the Sri Lankan context, the practice uses traditional methods and maintains the required accuracy through the estimator's experience.

Preparing a preliminary estimate within the context includes identifying project characteristics through available drawings, the client's brief, and discussions with the client. After that, the estimator prepares the estimate using past project data. The experience of the estimator mainly produces the necessary assumptions and adjustments. Further, it can be identified that several experienced estimators are using a combination of traditional methods as a customised method that suits the firm to maintain the accuracy and reliability of the estimate.

The model can be developed within the firm using an appropriate database and the necessary human resources. Further, the investors can make reliable decisions on the project at the initial stage by using ANN models for preliminary estimations. Also, the

higher accuracy and time efficiency are the most significant benefits of using ANN for preliminary estimations. A manual validation process was carried out to identify the accuracy of the developed ANN model. The best model was the Google Colaborotary model, which had the highest accuracy of 89.56%. Furthermore, the study used a comprehensive data set along with the expert review on the parameters, ensuring the reliability of the outcome of the study.

The outcome highlighted the requirements for input attributes related to location, price fluctuations, risk, and uncertainty to improve the accuracy of the preliminary estimation model as the limitations of this study. Location and price fluctuation changes can be included in the model using location indices, CIDA indices and inflation rates as the future research direction of this study.

ADDRESSING DATA MANAGEMENT CHALLENGES IN SRI LANKAN CONSTRUCTION INDUSTRY THROUGH BLOCKCHAIN INTEGRATION

W.M.N.D. Wijesundara[1], M. Thayaparan[2] and M.D.D. Costa[3]

ABSTRACT

The construction industry in Sri Lanka continues to face critical data management challenges due to fragmented systems, manual processes, and a lack of interoperability among digital platforms. These inefficiencies lead to delayed decision-making, data duplication, and reduced stakeholder trust. In response, blockchain technology has gained attention as a transformative digital solution capable of enhancing transparency, traceability, and security in construction data workflows. This study first explores the DM challenges in construction and then investigates the potential of integrating BC technology to address these DM challenges within the Sri Lankan construction sector. A mixed-method research approach was employed, comprising 35 quantitative questionnaires and 13 qualitative expert interviews with industry professionals. The findings identified several persistent DM challenges, including poor real-time data access, data ownership ambiguity, and cybersecurity risks, and such challenges were mapped against the core features BC such as decentralisation, immutability, auditability, and smart contracts. While practical deployment was not undertaken, the study presents a conceptual foundation for how BC can enhance construction DM. The research contributes to the broader discourse on digital transformation in construction by offering context-specific insights and strategic recommendations for future adoption of BC in Sri Lankan built environment.

Keywords: *Blockchain; Construction Industry; Data Management; Digital Transformation; Sri Lanka.*

1. INTRODUCTION

The construction industry is widely acknowledged as one of the most data-intensive sectors, relying heavily on consistent, accurate, and timely information exchange across the entire project lifecycle from initial conceptualisation, design, and procurement to construction, handover, and facilities management (Dauda et al., 2024; Tsay et al., 2022). Thus, efficient data management (DM) is essential to ensure that critical information is accessible, accurate, and timely to support planning, execution, monitoring, and control

of construction activities (Dauda et al., 2024; Antunes & Gonzalez, 2015). However, poorly managed data can result in significant inefficiencies such as delayed decisions, duplicated work, rework, budget overruns, and contractual disputes (Love et al., 2013).

In the context of Sri Lanka, the construction sector continues to rely heavily on fragmented and predominantly manual DM processes (Dilaksha et al., 2024). Although digital tools such as Building Information Modelling (BIM), Enterprise Resource Planning (ERP), and cloud-based storage platforms have been introduced in some projects, these are not uniformly adopted or fully integrated into everyday workflows (Hewavitharana et al., 2025; Mohanaraj et al., 2022). The sector's digital transformation is hindered by technological inertia, inconsistent adoption across departments, lack of skills, and insufficient regulatory and organisational frameworks (Bandara et al., 2024). These issues are compounded by concerns about data ownership, version control, interoperability, and the trustworthiness of shared project information (Turk, 2020). Systemic DM limitations necessitate innovative technological interventions that can address the root causes of inefficiency, fragmentation, and lack of transparency (Nawi et al., 2014). While advanced economies have increasingly adopted integrated digital platforms (Bandara et al., 2024) Sri Lanka's construction industry remains largely reliant on manual documentation, disconnected digital systems, and paper-based approvals. This disparity necessitates a context-sensitive evaluation of blockchain, which may offer different implementation pathways and benefits than in global settings (Elghaish et al., 2023).

Blockchain (BC) technology has recently gained attention as a potential game-changer in this regard. Initially developed for financial transactions, BC is now recognised across industries for its capabilities in ensuring secure, decentralised, and tamper-proof data environments (Perera et al., 2020; Punia et al., 2024; Shishehgarkhaneh et al., 2023). Features such as immutability, consensus verification, cryptographic encryption, and smart contract automation can significantly enhance data reliability, stakeholder trust, and process integrity in construction settings (Dauda et al., 2024; Shojaei, 2019; Nawari & Ravindran, 2019). However, the practical integration of BC into construction DM particularly in developing countries such as Sri Lanka remains underexplored. A critical gap exists in understanding how BC's capabilities can be aligned with local DM challenges, industry constraints, and stakeholder readiness (Perera et al., 2020; Gamage et al., 2024).

Given this context, this paper addresses two research objectives: 1) To identify challenges within current DM systems in Sri Lankan construction sector, 2) To assess the potential of BC technology as a solution to those challenges. This study provides strategic insights for leveraging BC to overcome Sri Lankan construction DM inefficiencies through targeted technological integration.

2. LITERATURE REVIEW

2.1 DATA MANAGEMENT CHALLENGES IN CONSTRUCTION INDUSTRY

The construction industry is a complex, fragmented, and multidisciplinary domain involving various stakeholders such as clients, contractors, consultants, subcontractors, suppliers, and regulatory agencies working across distinct project phases (Nawi et al., 2014). This collaborative environment generates diverse data types such as architectural

plans, structural designs, cost estimates, contracts, and maintenance logs, which must be effectively managed in real time (Yousif et al., 2021).

In recent years, the construction industry has transitioned from manual DM to digital platforms such as BIM, ERP systems, and cloud databases to improve data integration and access (Vararean-Cochisa & Crisan, 2024). However, in developing countries like Sri Lanka, adoption remains inconsistent due to infrastructural limitations, skills gaps, and resistance to change (Jaiswal et al., 2024). While advanced economies such as the UK, Singapore, and China have successfully integrated BC with digital systems, Sri Lanka continues to face low ICT penetration and weak regulatory support (Gamage et al., 2024; Bandara et al., 2024). These disparities affect BC's practical applicability. Despite digital tools' potential to improve productivity and transparency, persistent challenges such as poor interoperability, limited real-time access, cybersecurity risks, and ambiguous data ownership undermine efficient DM (Dauda et al., 2024; Chaganti et al., 2022). These issues highlight the need for secure, decentralised solutions tailored to the local context (Hua et al., 2025).

Table 1 outlines the key DM challenges identified in the literature, which form the basis for assessing BC's potential as a strategic response in addressing such challenges.

Table 1: Key DM challenges in the construction industry

Challenge	Description	Citation
Real-Time Data Access	Disconnected systems delay updates on-site and off-site, resulting in outdated decisions, rework, and project delays.	[1], [3], [11]
Data Sharing and Collaboration	Fragmented stakeholder networks and proprietary data formats hinder smooth collaboration, limiting efficiency in multi-party coordination.	[2], [7], [9], [11]
Data Security and Cyber Threats	Increasing reliance on digital systems exposes projects to phishing, ransomware, and data leaks due to inadequate cybersecurity practices.	[3], [7], [14]
Data Ownership and Responsibility	Ambiguity in contracts regarding who controls or updates data creates accountability gaps and potential legal conflicts.	[2], [3], [7]
Data Quality and Accuracy	Manual entries, lack of validation processes, and poor integration lead to inaccurate data, which affects scheduling, budgeting, and claims.	[3], [4], [7], [13], [9]
Adopting and Implementing Technology	Resistance to change, insufficient digital skills, and unclear ROI slow down the implementation of integrated DM systems.	[8], [12]
Data Collection and Integration	Data is often collected through isolated tools or paper-based methods, leading to inconsistencies and duplication across the lifecycle.	[4], [10], [15]
Cost Management	Disparate data sources and delayed reporting lead to budget overruns, inaccurate estimates, and delayed payments.	[2], [5]
Compliance with Regulations	Without tamper-proof records or audit trails, firms face challenges in meeting regulatory, contractual, and sustainability reporting requirements.	[2], [9], [13]

Challenge	Description	Citation
Interoperability of Systems	Use of non-standard software and platforms causes integration issues, requiring manual data transfers between incompatible systems.	[3], [8]
Version Control and Document Management	Poorly managed document versions result in miscommunication, outdated approvals, and project disputes.	[1], [2], [10], [12]
Training & Skills Gaps	Many professionals lack the skills to adopt emerging digital tools, including BIM and BC, limiting their practical implementation.	[1], [2], [11]

[1]-(Abu-Reishah & Hiyassat, 2021), [2]-(Bhavsar et al., 2018), [3]-(Dauda et al., 2024), [4]-(de Bruijn & Janssen, 2017), [5]-(Halttula et al. 2020), [6]-(Jaiswal et al., 2024), [7]-(Luo, 2022), [8]-(Nawari & Ravindran, 2019), [9]-(Pham et al., 2023), , [10]-Shojaei, 2019 [11]-(Tanga et al., 2021), [12]-(Turk, 2020), [13]-(Vararean-Cochisa & Crisan, 2024), [14]- (Yao & De Soto, 2024), [15]- (Zhang et al., 2017)

The challenges prove persistent and multi-dimensional, cutting across technical, organisational, and cultural domains. The identification of these challenges by academic researchers enables an assessment of how BC can be applied for their resolution.

2.2 POTENTIAL OF BLOCKCHAIN TO ADDRESS DATA MANAGEMENT CHALLENGES

BC, originally conceptualised by Nakamoto (2008) for peer-to-peer financial transactions, has evolved into a versatile digital infrastructure applicable across various sectors. It operates as a decentralised, distributed ledger that records transactions in cryptographically linked blocks. Each block is time-stamped and validated through consensus algorithms, which ensures data integrity, transparency, and immutability (Christidis & Devetsikiotis, 2016). Within the construction industry where project success hinges on real-time, accurate, and trustworthy data exchanges BC offers a set of technological features that directly respond to the sector's persistent DM challenges. The following sub-sections outline how these core features can provide targeted solutions aligned with construction project workflows:

- Decentralisation: BC reduces single points of failure by distributing data storage and validation across a peer-to-peer network. Consensus mechanisms replace central authority, enhancing traceability and system reliability (Karafiloski & Mishev, 2017; Singh et al., 2023; Sood et al., 2024).
- Transparency: BC promotes stakeholder accountability by providing real-time, tamper-evident access to transaction records. This is particularly valuable in public construction projects, reducing corruption and fostering trust (Awaysheh & Klassen, 2010; Perera et al., 2021).
- Performance and scalability: Permissioned platforms like Hyperledger Fabric support high transaction throughput. Smart contracts automate key processes tendering, procurement, payments streamlining construction workflows and reducing delays (Alharby & Van Moorsel, 2017; Bondi, 2000).
- Trust: Built through decentralised consensus, which ensures that no data entry is accepted without validation by a network majority. This process reduces

misinformation, reinforces mutual credibility among project parties, and enhances cooperative decision-making (Tanga et al., 2022).

- Security: Enhanced via cryptographic protocols, such as SHA-256, which protect sensitive project documents from tampering and unauthorised access. Peer-to-peer validation further ensures that only verified entries become part of the immutable record (Sood et al., 2024).
- Immutability: Guarantees that once information is entered into the BC, it cannot be modified without collective agreement. This feature is critical for managing design revisions, procurement logs, and change orders, as it preserves the integrity of historical data (Underwood, 2016; Wu et al., 2019).
- Auditability: Achieved through time-stamped, sequential data blocks that enable easy tracking of activities such as inspection reports, delivery schedules, and contractual milestones. This feature enhances regulatory compliance and internal project governance (Selvanesan & Satanarachchi, 2023; Collinge et al. 2009).

Overall, BC's technological enablers provide a transformative framework for solving critical DM issues in construction, offering improved real-time access, interoperability, security, and stakeholder collaboration.

3. METHODOLOGY

This study adopted a mixed methods design to investigate the potential of BC in addressing DM challenges identified within Sri Lanka's construction industry. As such both structured questionnaires and semi-structured interviews were used to collect quantitative and qualitative data, respectively. Structured questionnaires distributed to 55 professionals, with 35 valid responses were analysed using the Relative Importance Index (RII) method to rank key DM challenges identified using the comprehensive literature review. While the sample size is modest, it is considered adequate for exploratory research in construction studies where respondents are purposefully selected based on their domain knowledge (Vasileiou et al., 2018). Similar studies in Sri Lanka have also employed comparable sample sizes to examine digitalisation in construction (Gamage et al., 2024). A non-probabilistic purposive sampling method was used to ensure participants had experience in digital tools and DM processes. The sample included professionals actively involved in data-driven decision-making, making the responses highly relevant. Additionally, as younger professionals tend to engage more with digital platforms, the selection did not limit based on years of experience. Table 2 presents the experience breakdown and response rates, showing that a majority of respondents had less than five years of experience.

Table 2: Experience and response rate of respondents for the questionnaire

Experience (Years)	Distributed	Valid responses	Response rate (%)
0–5 years	25	20	80%
6–10 years	15	8	53%
11–15 years	10	4	40%
Over 15 years	5	3	60%
Total	55	35	63.64%

To complement the survey findings and add more richness to the identified challenges, 13 expert interviews were conducted using a semi-structured format. The experts included construction professionals familiar with DM processes and IT experts with BC knowledge. The construction professionals have comparatively limited knowledge about BC technology in Sri Lanka, as those technologies are not adopted to the construction. Due to their limited knowledge, they are unable to see the full potential a BC can bring to improve DM challenges. To address this limitation the authors also interviewed IT experts who had provided the technical insights on BC in addressing DM challenges. The researcher has played a key role during the interview in terms of bridging the knowledge gap about BC and DM in construction to both construction and IT experts, respectively. The interviews offered qualitative insights into the feasibility, barriers, and strategic integration of BC in the local context. Manual content analysis was used to analyse the qualitative data. The respondent profile in terms of years of experience and the knowledge / experience on the key areas of the research, i.e., BC, DM, construction are summarised in Table 3.

Table3: Profile of interviewees

Respondent	Total work experience (Years)	Knowledge and Experience on the key areas related of the research
CI1	6+	Construction, BC technology, and DM
CI2	6+	Construction and DM
CI3	9+	PhD in BC for DM in construction
CI4	5-10	Experience in both BC and DM in construction
CI5	5+	BC for Sri Lankan tendering processes
CI6	15+	Construction industry and DM experience, PhD research in BC
CI7	8+	PhD in BC
CI8	6+	Experience in both DM and BC
IT1	7+	Construction-based IT products, BC experience
IT2	5+	Construction data analyst, AI solutions for DM
IT3	7+	BC technology
IT4	3-4	Supply chain BC solutions
IT5	5+	Web-based application development

4. FINDINGS AND DISCUSSION

4.1 CURRENT DATA MANAGEMENT CHALLENGES

The critical DM challenges identified in the literature were contextualised to Sri Lankan construction using both quantitative RII analysis and qualitative content analysis. Table 4 outlines these challenges, combining quantitative rankings with qualitative validation to highlight key problem areas affecting efficiency, accuracy, integration, and decision-making in construction projects in Sri Lanka.

Table 4: Challenges in DM with RII and interview validation

DM Challenge	RII	CI1	CI2	CI3	CI4	CI5	CI6	CI7	CI8	IT1	IT2	IT3	IT4	IT5
Cost Management	0.794	✓	✓	✓		✓	✓	✓	✓				✓	
Data Security and Cyber Threats	0.761			✓	✓						✓			
Version Control and Document Management	0.761		✓											✓
Interoperability of Systems	0.755	✓	✓	✓		✓	✓	✓	✓	✓				
Real-Time Data Access	0.729	✓		✓	✓	✓	✓	✓		✓	✓	✓	✓	
Training and Skills Gaps	0.729						✓							
Adopting and Implementing Technology	0.723		✓			✓		✓	✓		✓	✓	✓	✓
Data Collection and Integration	0.716	✓	✓				✓			✓			✓	
Data Quality and Accuracy	0.703	✓	✓	✓	✓			✓	✓	✓		✓	✓	✓
Compliance with Regulations	0.703		✓		✓	✓	✓	✓		✓	✓	✓		
Data Sharing and Collaboration	0.690	✓	✓	✓	✓			✓	✓	✓	✓	✓	✓	
Data Ownership and Responsibility	0.684		✓	✓	✓	✓	✓		✓		✓	✓	✓	✓

These findings provide a structured foundation for deeper analysis of each significant challenge which are discussed below.

Among all, the cost management has been ranked as the most significant challenge which was also agreed by the experts to a certain extent. It is a leading challenge due to poor real-time tracking and budget visibility. CI6 stated, *"delays happen because of unclear cost tracking and improper budget allocation."* IT4 noted, *"BC can improve real-time cost updates,"* while CI8 warned that *"high implementation costs may deter smaller firms,"* highlighting both the promise and the barrier of adopting BC solutions.

In close alignment, cybersecurity emerged as another serious concern, where firms are increasingly storing sensitive project data on cloud platforms without adequate safeguards. IT1 stated, *"security breaches are not rare anymore… but most local firms don't have dedicated cybersecurity teams."* These insights reveal critical vulnerabilities that not only threaten data integrity but also expose firms to compliance failures and reputational harm.

Equally critical is the issue of version control and document management, with teams often working on outdated documents, leading to conflicts and added costs. CI2 noted, *"multiple document revisions between systems create chaos,"* while IT1 stated, *"BC enables transparent monitoring of updates,"* ensuring version accuracy. The lack of unified tracking systems poses operational and legal risks across project environments.

Interoperability was also highlighted as a major barrier to digital transformation in the Sri Lankan construction sector. Respondents noted that many existing digital platforms, including BIM and ERP systems, operate in isolation due to a lack of integration standards and APIs. CI6 explained, *"our BIM model can't talk to the procurement system,*

we end up duplicating everything manually." IT3 reinforced this issue, stating, *"without integration tools, digital systems just become digital islands."* These silos lead to inefficiencies in communication, data duplication, and an overall disjointed workflow that slows down collaboration.

Another pressing challenge is real-time data access. In Sri Lankan construction projects, delays in accessing up-to-date information frequently interrupt workflows, delay procurement, and cause billing inconsistencies. Survey findings confirmed this as a major issue.CI3 noted, *"we face major delays because the site team and consultants often work with different versions of data,"* while CI6 added, *"even printing outdated drawings has caused rework."* These inconsistencies not only increase the risk of errors and miscommunication but also lead to duplicated work, claims disputes, and reduced stakeholder confidence in project documentation.

Furthermore, digital literacy and skills gaps emerged as a recurring theme in both survey and interview data. CI2 mentioned, *"we invested in ERP, but staff still rely on Excel. They don't trust the new system."* IT3 reinforced this, stating, *"many project managers are afraid of making mistakes, they avoid digital platforms altogether."* Without structured training and change management, firms struggle to shift from traditional practices to efficient digital workflows.

These findings confirm the complex, interrelated nature of DM challenges in Sri Lanka's construction industry.

4.2 THE POTENTIAL OF BLOCKCHAIN TO ADDRESS DATA MANAGEMENT CHALLENGES

Survey and interview findings show strong optimism for BC in addressing construction DM issues. With 65.9% rating BC as "likely" or "extremely likely" to help, no respondents found it ineffective (Figure 1).

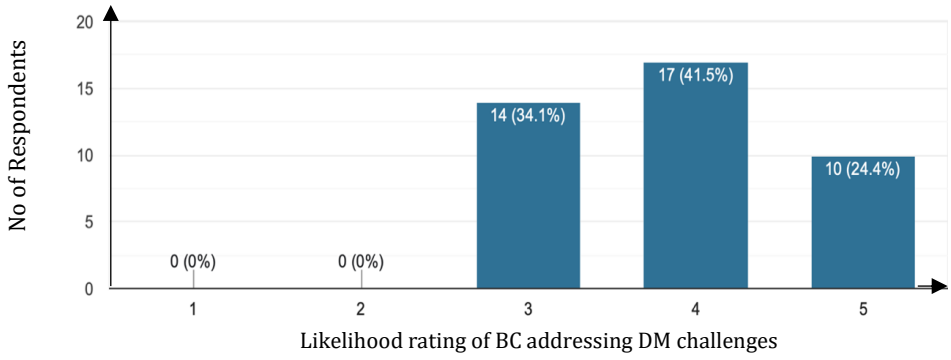

Figure 1: Likelihood rating of BC addressing DM challenges from questionnaire analysis

These findings form the foundation for evaluating specific BC features and their alignment with the critical challenges identified earlier. This subsection further investigates key features of BC such as security, auditability, transparency, decentralisation, performance & scalability, immutability, trust and disintermediation to directly map with construction DM.

To begin with, security was highlighted as a significant challenge, BC can address this through advanced cryptographic protocols, such as SHA-256 and asymmetric encryption,

to authenticate access and detect tampering. IT1 emphasised, *"once a file is in the chain, nobody can alter it without permission. That's the kind of integrity we need for compliance and audits."* CI4 added, *"without real encryption, it's just a data dump, BC gives structure and defense."* These features are critical for safeguarding procurement records, site data, and sensitive communications.

In addition to security, auditability is a core benefit of BC. BC's timestamped entries and full historical traceability support compliance with legal, regulatory, and quality standards. CI7 remarked, *"the audit trail in BC can reduce the effort needed for dispute resolution or compliance reviews."* By maintaining unalterable records of contracts, transactions, and communications, BC offers greater certainty in audits and builds confidence among clients and government agencies.

Closely linked to auditability is transparency, which directly impacts collaboration and accountability. BC allows all participants to trace data origins, monitor alterations, and verify user access through immutable logs. As CI5 noted, *"when people can see exactly who changed what and when, trust builds naturally. BC can offer that."* IT2 echoed, *"visibility builds confidence, when data access is logged, people stop hiding updates."* In collaborative, multi-party environments, BC thus fosters accountability and encourages proactive data sharing and improved coordination.

Equally important is decentralisation, a foundational attribute of BC. Its decentralised nature ensures that data is stored and updated across multiple nodes, allowing all authorised users to access synchronised, real-time information. This feature directly addresses the challenge of outdated or inconsistent data. CI3 explained, *"BC's structure means everyone works off the same real-time ledger, reducing delays caused by outdated files."* CI6 added, *"the data flows immediately once verified; you don't need to chase it across departments."* This systemic improvement enhances workflow continuity, particularly during procurement and billing milestones.

Moreover, BC offers high performance and scalability, especially through API-based interoperability. This capability is crucial in resolving challenges around fragmented software ecosystems. Interoperability issues affect nearly every construction firm surveyed, with disparate tools such as BIM, ERP, and project management software often functioning in isolation. IT5 highlighted, *"with smart contracts, you can link milestones in BIM to payment releases in ERP. It's like getting everything to finally speak the same language."* The flexible architecture of BC allows tailored implementation, making cross-platform automation more achievable than with traditional systems.

When it comes to immutability, BC plays a vital role in addressing version control issues. Once data is entered into the BC, it cannot be altered without consensus, effectively protecting records from unauthorised edits. CI6 commented, *"the immutability of BC means we can trace every step of a design change, every update to a BOQ, without confusion."*

Furthermore, trust is a central factor in any data-sharing environment, and BC enhances this through verifiable, tamper-proof records and transparent workflows. CI5 mentioned that transparency naturally builds trust, while CI2 reflected, *"yes, training is needed, but once teams see the system protecting their input and giving credit, adoption becomes easier."* Trust increases when team members can independently verify data without relying on intermediaries, fostering a sense of ownership and accountability.

Finally, BC facilitates disintermediation by eliminating unnecessary intermediaries in data validation and approvals. This is especially relevant in projects involving multiple tiers of subcontractors and consultants. IT2 and CI6 emphasised that disintermediation not only cuts costs but also enhances transparency and decision-making speed across the value chain.

In summary, BC's unique features directly respond to longstanding challenges in construction DM, offering a structured and secure pathway for digital transformation.

4.3 MAPPING THE BC FEATURES WITH DATA MANAGEMENT CHALLENGES

The Figure 2 visually represents summary of the analysis discussed above about BC features and DM challenges in the construction industry. The color-coded cells indicate the level of endorsement from respondents, showing which BC features are widely recommended, highly rated, strongly agreed upon, or mentioned by the respondents, reinforcing the survey findings that BC can significantly enhance DM in construction projects.

DM Challenges \ BC Feature	Security	Auditability	Transparency	Decentralisation	Performance & Scalability	Immutability	Trust	Disintermediation
Cost Management								
Data Security and Cyber Threats								
Version Control and Document Management								
Interoperability of Systems								
Real-Time Data Access								
Training and Skills Gaps								
Adopting and Implementing Technology								
Data Collection and Integration								
Data Quality and Accuracy								
Compliance with Regulations								
Data Sharing and Collaboration								
Data Ownership and Responsibility								

Minimally recommended- Chosen by 4 or fewer respondents	
Moderately recommended - Chosen by 5–9 respondents	
Mostly recommended - Chosen by 10 or more respondents	

Figure 2: Correlation between BC features and DM challenges in Sri Lankan construction industry

Figure 2 indicates that BC features are contributing to address the DM challenges, though the extent of contribution from each feature varies from challenge to challenge. It is also observable that each DM challenge can be addressed by using at least one of the BC features. This clearly indicates the potential of integrating BC technology to address these DM challenges within the Sri Lankan construction sector.

5. CONCLUSIONS AND RECOMMENDATIONS

This paper explored the DM related challenges in Sri Lankan construction sector and assessed how BC technology could help address key challenges. Findings from both questionnaire survey and expert interviews confirmed most of the critical DM challenges identified in the literature, that include lack of real-time data access, poor system interoperability, cybersecurity risks, and document version inconsistencies. These inefficiencies significantly undermine project performance, collaboration, and trust among stakeholders.

BC technology demonstrates strong potential in mitigating these challenges through its core features such as security, auditability, transparency, decentralisation, performance & scalability, immutability, trust and disintermediation. The study highlighted that BC could ensure synchronised access to real-time data, secure information exchange, and enhance traceability across project phases. It also provides a robust mechanism for document management, reducing version conflicts and ensuring accountability through immutable records.

Although the implementation of BC was not explored in depth, the study concludes that BC is a promising technological intervention with high potential and capability of addressing fundamental DM challenges in the construction industry. Future research should explore real-world pilot projects, implementation strategies, and the regulatory and organisational support needed to operationalise BC solutions within Sri Lankan construction context.

AN INVESTIGATION INTO EFFECTIVE ENERGY BEHAVIOR CONTROL STRATEGIES IN THE APPAREL MANUFACTURING SECTOR

N. Premananth[1] and S.D.A. Soorige[2]

ABSTRACT

Energy consumption in the apparel industry is high, driven by intense usage of Heating, Ventilation, and Air Conditioning (HVAC) systems, lighting, and machines. Given its intensive nature and high carbon footprint, implementing efficient energy behavioural control strategies is crucial for advancing sustainability goals. This study identifies, evaluates, and rates thirteen strategies spanning technological, managerial, legal, and social domains through a comprehensive literature analysis and expert validation using the Relative Importance Index (RII) technique. Findings demonstrate a high preference for technologically driven interventions such as Artificial Intelligence (AI) and machine learning based predictive control, automation and smart controls, and smart metering systems, which enable precision, scalability, and real-time adaptability. Mid-tier tactics like incentive programs, dashboards, and training were regarded vital, while behaviour focused, legal, and social initiatives were ranked less effective due to perceived complexity, longer return scopes, and lower direct impact. The study underlines the necessity of a hybrid implementation approach that combines high impact technology with structured behavioural support mechanisms to foster sustainable energy practices. Limitations include potential sample bias in expert replies and a focus on large-scale manufacturing contexts, which may not completely represent issues experienced by small and medium enterprises (SMEs). Future studies should explore contextual barriers to strategy adoption across different organizational sizes and cultures and analyse the long-term performance of integrated technical behavioural models.

Keywords: *Apparel manufacturing; Energy efficiency; Energy behaviour control strategies; Sustainability.*

1. INTRODUCTION

The building sector is a dominant contributor to global energy consumption, accounting for approximately 40% of total energy use and 30% of carbon dioxide (CO_2) emissions (Schito & Lucchi, 2023). Substantial energy demand stems primarily from heating, cooling, lighting, and other operational activities powered by fossil fuels (Bodziacki et al., 2024). Due to urbanization and economic growth accelerating energy demand, policymakers worldwide are prioritizing energy efficiency measures in urban planning to

[1] Undergraduate, Department of Building Economics, University of Moratuwa, Sri Lanka, niveathapremananth3@gmail.com
[2] Lecturer, Department of Facilities Management, University of Moratuwa, Sri Lanka, sooriged@uom.lk

mitigate climate change and reduce ecological footprints (Umoh et al., 2024). Despite advancements in energy efficient technologies such as high-performance Heating, Ventilation, and Air Conditioning (HVAC) systems, Light emitting diode (LED) lighting, and smart building automation, a persistent gap remains between projected and actual energy performance due to human behaviour (Kovalchuk & Shcherbakova, 2024; Ekim et al., 2023).

While technological innovations like improved insulation, airtight construction, and solar panels enhance energy efficiency, their full potential is often undermined by occupant behaviour (Amasyali & El-Gohary, 2021). Studies indicate that fluctuating behaviour, such as not turning off the lights, adjusting thermostats too much, or switching off automated devices, is likely to discredit energy saving potential (Xu et al., 2023). Hence, the discrepancy is known as the "energy performance gap," as it focuses on the implementation of a combined approach that involves technological advancements and behaviour (Bäcklund et al., 2023).

As per that research suggests that psychological factors and behaviour have the greatest contribution to energy consumption patterns (Ekim et al., 2023). As per that, activities of end users with lighting, HVAC, and appliances contribute significantly to total energy consumption and habits, awareness, and incentives must be considered along with technical measures (Maghsoudi Nia et al., 2022). For instance, energy feedback systems with real-time energy feedback were identified to reduce usage by 14.8%, demonstrating the effectiveness of data informed, individual specific interventions (Vijlbrief et al., 2022). Similarly, gamification, nudging behaviour like reminders and incentives, and reward schemes can instil long-term energy-saving habits (Li et al., 2024; Maghsoudi Nia et al., 2022).

The apparel industry is one of the most energy-consuming sectors, where air conditioning alone accounts for 46% of the energy used in manufacturing plants (Jananthan et al., 2006). In addition, textile processing requires enormous water, fuel, and electricity consumption, thus posing a massive industrial carbon footprint (Garg & Bhardwaj, 2024).

This study aims to bridge the gap between theoretical energy saving models and real-world applications by developing and assessing viable energy behavioural control strategies within the apparel manufacturing sector. The paper provides a review of relevant literature, followed by a full discussion of the research methods. It then provides the findings and includes a discussion on their implications, closing with practical insights and recommendations for further implementation and study.

2. LITERATURE REVIEW

2.1 ENERGY CONSUMPTION IN APPAREL MANUFACTURING

The apparel manufacturing business is a major industry in world economies but is also famously energy intensive, as it directly impacts production costs, ecological sustainability, and company effectiveness (Yılmaz et al., 2024). The apparel industry is renowned for having multifarious operational processes that include spinning, weaving, dyeing, finishing, cutting, sewing, and pressing and wet processing, particularly dyeing and finishing, which constitutes a major energy intensive industry, using a considerable portion of the industry's total energy consumption (Ajam & Khoshgoftar Manesh, 2025).

In extensive apparel manufacturing facilities, producers typically employ energy efficient technology, automation, and renewable energy sources to enhance consumption efficiency, whereas small and medium sized enterprises encounter challenges in adopting these strategies due to financial and technical constraints (Ketenci & Wolf, 2024).

As sustainability gains popularity, factories are increasingly using energy behaviour control tactics and data-driven energy management systems to boost efficiency and comply with environmental standards, and these approaches employ sophisticated technology, such as Artificial Intelligence (AI) and Internet of Things (IoT), to optimize energy consumption and eliminate waste, eventually supporting sustainability goals.

2.2 SIGNIFICANCE OF ENERGY BEHAVIOUR CONTROL STRATEGIES

Energy behaviour control strategies offer significant economic benefits by optimizing industrial processes, reducing energy costs, and enhancing productivity. Businesses that adopt these strategies improve resource efficiency, mitigate market risks, and strengthen competitiveness (Gitelman et al., 2019). Non-price interventions, such as energy use labelling and feedback systems, further encourage energy efficient behaviors, yielding long term economic returns (Zheng et al., 2022).

As for environmental impact, integrating psychological variables such as behavioural changes and persuasive technology (IoT, Smart metering and AI) promotes user engagement, ultimately promoting environmentally friendly behaviours and contributing to sustainable development (Chiu et al., 2020). Moreover, energy behaviour management measures are crucial for sustainable energy consumption, reducing environmental impact, and fostering conservation, ultimately reducing carbon emissions, helping ameliorate climate change and enhancing ecological health (Sweeney et al., 2018).

Practicing energy behaviour control strategies is significant because it improves building practitioners' sense of behavioural control, which positively impacts their intent of complying with energy performance standards, ultimately leading to better compliance outcomes than the minimum requirements in building design (Lu et al., 2024). Integrating energy behaviour management strategies, such as noise reduction techniques for Battery, Energy Storage Systems are vital for achieving regulatory compliance requirements while guaranteeing community acceptability and limiting the impact on residential areas (Martinez et al., 2013).

2.3 ENERGY BEHAVIOUR CONTROL STRATEGIES

2.3.1 Technological Strategies

Recent improvements in smart metering and IoT based systems have enabled real-time energy tracking, automated alarms, and comparative usage analysis, which are often attributed with boosting industrial energy efficiency (Mirani et al., 2024). While these technologies outperform traditional human monitoring in scalability and data precision, their performance strongly depends on organizational capability to act on the insights generated. In SMEs, the lack of competent individuals or integration frameworks sometimes limits their impact, a topic underexplored in current literature (Hattori et al., 2019). Automation solutions such as variable speed drives are also commonly referenced for optimizing motor and pump operations, eliminating unnecessary energy waste (Singhal & TR, 2023). However, most studies focus on their implementation in developed nations or highly mechanized industries, with scant investigation of their performance in

labour intensive sectors like clothing manufacture. This is an important research gap, as the operational context can considerably influence system performance (Hattori et al., 2019).

Behavioural nudging using apps and digital notifications is another new method, leveraging psychological triggers to induce change (Cellina et al., 2024). Although studies highlight positive short-term effects, others point to uneven engagement and user fatigue, suggesting that these technologies may lack sustainability if not linked with management reinforcement or tangible incentives (Ubachukwu et al., 2023). These discrepancies underscore the necessity for hybrid approaches that mix digital interventions with organizational support structures (Zhao, 2024).

2.3.2 Managerial Strategies

Employee training programs are crucial for fostering energy conscious behaviours in the workplace (Kotsopoulos et al., 2023). Effective training integrates behavioural psychology principles to overcome cognitive biases and reinforce energy saving habits (Canova & Manganelli, 2020). Performance monitoring and feedback systems, when combined with smart metering, sustain energy reductions of approximately 5% (Schleich et al., 2017). Energy conservation is further encouraged via incentive-based programs, which include monetary awards as well as nonmonetary motivators like environmental awareness campaigns (Asensio & Delmas, 2015).

2.3.3 Legal and Social Strategies

Energy conservation agreements between governments and industries facilitate negotiated efficiency targets, offering flexibility and cost-effective compliance (Dernbach et al., 2011). Policy enforcement, when combined with behavioural insights, enhances regulatory adherence and promotes sustainable practices (Hajialigol et al., 2023). Social strategies, such as recognition programs and community engagement, leverage social norms to motivate energy saving behaviours (Bonan et al., 2020). As well as collaborative goal setting initiatives in residential and organizational settings have achieved energy savings exceeding 20% (Iweka et al., 2019).

2.4 IMPLEMENTATION BARRIERS AND CHALLENGES

2.4.1 Technical Barriers

The deployment of energy behavioural control systems confronts various technological hurdles, including infrastructure limits due to incompatible data formats, security and privacy concerns, and the necessity for robust communication networks (Chillayil et al., 2022; Reynolds et al., 2017). Integration with existing systems is challenged by legacy technologies, rigid operational models, and the difficulties of adding predictive control algorithms (Huckebrink & Bertsch, 2021). Additionally, a lack of technical skills inhibits deployment, notably in installing and maintaining data from devices like submeters and building automation systems (Adu-Kankam & Camarinha-Matos, 2020; Barido et al., 2020). Maintenance and upgrades further complicate implementation, as malfunctioning systems and complex controls annoy building workers, diminishing the efficiency of energy saving measures (Yılmaz et al., 2024).

2.4.2 Organizational Barriers

Organizational obstacles include high initial investment costs, which dissuade stakeholders owing to unclear financial returns and a propensity for limiting capital expenses over long term efficiency (Bensouda & Benali, 2022). Resistance to change among employees, coming from psychological and social issues, also obstructs adoption, requiring appropriate communication and support to overcome (Bäcklund et al., 2023). A lack of management commitment increases these challenges, resulting in poor resource allocation and insufficient strategic planning for energy saving programs (Khafiso et al., 2024; Russell et al., 2020). Additionally, restricted resources and time limits hinder decision making, requiring supportive policies and accessible information to induce behavioural shifts (Bensouda & Benali, 2022).

2.4.3 Long term Sustainability Challenges

Sustaining behavioral improvements over time remains difficult due to psychological resistance, motivational gaps, and the need for constant assistance (Tsuda et al., 2017; Cash et al., 2023). Continuous monitoring is crucial but problematic due to data disparities and the complexity of tracking energy conservation outcomes (Chen & Nunes, 2023). Rapidly emerging technologies present acceptance barriers, particularly for smaller enterprises with limited resources, while knowledge gaps among consumers inhibit proactive engagement (Borowski, 2020). Staff turnover further undermines long term sustainability, as organizational culture and training efficacy influence the retention of energy management techniques (Brabson et al., 2019).

3. RESEARCH METHODOLOGY

This study adopted a quantitative approach, sequential exploratory, grounded in a quantitative dominant approach, to identify and prioritize behavioural energy management strategies within the apparel manufacturing industry (Levitt et al., 2018).

The methodology had three essential phases: strategy identification from literature review, validation through peer review by experts, and a quantitative ranking procedure. A thorough literature analysis was undertaken to compile a diverse array of energy behaviour management strategies applicable to industrial contexts, namely in apparel manufacturing. The review concentrated on peer-reviewed academic journals, industrial case studies, government publications, and best practice manuals released in the past decade. The review yielded 13 distinct strategies, which were then categorized into four thematic domains: technological, managerial, legal, and societal. The use of classification was intended to facilitate a holistic understanding of behavioural influences on energy efficiency (Thollander & Palm, 2018).

Further to the literature review, the identified strategies were corroborated and evaluated by expert opinion. A systematic questionnaire was prepared and disseminated among a selected group of energy professionals, including energy managers, engineers, facilities managers, and university scholars focusing on sustainability and industrial energy efficiency. A total of 40 specialists were recruited to participate in the study. The participants were chosen by purposive sampling, ensuring the inclusion solely of individuals with direct experience in energy management in industrial or commercial environments (Etikan, 2016). This selection method yielded a wide range of findings, enabling the research to encompass many views within the sector.

The questionnaire offered experts to score the 13 techniques based on their perceived effectiveness in real-world apparel manufacturing scenarios. Each participant was asked to assign a rank from 1 to 13, with 1 being the most effective method and 13 being the least effective, which is suitable for decision making and priority setting studies in energy research (Kassem et al., 2020). The purpose was to reflect on the practical prioritization of solutions as observed by individuals actively involved in energy related decision making and implementation.

To assess the responses, the Relative Importance Index (RII) approach was applied. This technique is widely used in construction and behavioural energy research to determine relative significance based on expert input (Kassem et al., 2020). The RII was determined using the formula:

$$RII = \frac{\sum W}{A \times N} \qquad Equation\ (1)$$

Where, W = constant expressing the weighting given to each response, A = highest weighting and N = total number in the responses.

Where W is the weight provided to each approach by respondents, A is the highest possible weight (in this case, 13), and N is the total number of respondents. The resulting RII scores were used to rank the solutions from most to least effective, presenting a clear indication of industry consensus on priority activities for behavioural energy control.

Ethical considerations were thoroughly addressed throughout the research process. Participation was entirely voluntary, and all respondents were informed of the study's goal and use of their responses. No personal or sensitive information was collected, and all replies were kept anonymous to maintain confidentiality. These processes guaranteed that the research was done in a manner that respects both academic integrity and the rights of the participants.

4. RESEARCH FINDINGS AND ANALYSIS

Through a comprehensive literature analysis, various energy behaviour control strategies have been identified and divided into four primary domains as technological, managerial, legal, and social strategies. Technological strategies include smart metering and monitoring systems, automation and smart controls, behavioural nudges through apps and notifications, energy dashboards and visualization tools, and AI and machine learning based predictive control, which leverage real-time data and automation to optimize energy efficiency. Managerial solutions focus on organizational interventions such as employee training programs, performance monitoring and feedback systems, and incentive-based programs to develop energy conscious behaviours. Legal strategies comprise energy conservation agreements and policy enforcement, which establish legislative frameworks to ensure compliance with energy saving initiatives. Lastly, social tactics encompass social recognition programs, community participation and education, and joint goal formulation, attempting to develop a culture of sustainability through collective action and awareness. These solutions jointly target both technological and human centric aspects of energy management, offering a holistic approach to reducing energy usage in industrial settings.

In the next step of the analysis, the identified energy behaviour control strategies were subjected to expert validation to assess their real-world effectiveness. According to that, the rankings were used to calculate the RII value of the strategies.

$$RII = \frac{\sum W}{A \times N} \qquad Equation\ (2)$$

Σ Scores for a Factor, this symbol (Sigma) represents the sum of all ranking that given to a specific strategy by all respondents. Higher ranking shows higher efficiency in normal context. Since lower original ranks (1, 2, 3...) indicate higher efficiency**,** invert the ranks.

For each strategy (1 to 13),

Inverted Score (W) = 14 - Original Rank

So, for AI ΣW = (14-7) +(14-7) +(14-13) +(14-2) +(14-9) +(14-13) +……+(14-3)

= 394

Based on the calculation of RII, Table 1 shows the RII rate of energy behaviour control strategies.

Table 1: RII rate of energy behaviour control strategies

Strategies	Highest Rank	Number of Responses	Weight of Strategy	RII	Rank
AI and Machine Learning Based Predictive Control	13	40	464	0.892	1
Automation and Smart Controls	13	40	423	0.813	2
Smart Metering and Monitoring Systems	13	40	394	0.758	3
Incentive based programs	13	40	370	0.712	4
Energy Dashboards and Visualization Tools	13	40	340	0.654	5
Employee training programs	13	40	324	0.623	6
Performance monitoring and feedback systems	13	40	306	0.588	7
Behavioural Nudges Through Apps and Notifications	13	40	286	0.550	8
Policy Enforcement	13	40	256	0.492	9
Energy Conservation Agreements	13	40	234	0.450	10
Social Recognition Programs	13	40	200	0.385	11
Community Engagement and Education	13	40	164	0.315	12
Collaborative Goal Setting	13	40	70	0.150	13

The strategy with the highest RII is AI and Machine Learning Based Predictive Control (0.892), signifying its considerable importance in contemporary energy optimisation initiatives. Subsequently, Automation and Smart Controls (0.813) and Smart Metering and Monitoring Systems (0.758) underscore the increasing focus on technology driven

solutions. Incentive Based Programs (0.712) and Energy Dashboards and Visualisation Tools (0.654) are highly ranked strategies, indicating that both motivation and visibility are crucial in promoting energy efficiency. Mid-level tactics encompass Employee Training Programs, Performance Monitoring, and Behavioural Nudges, highlighting the significance of human elements in conjunction with technical instruments. Policy Enforcement, Energy Conservation Agreements, and Social Recognition Programs rank lower on the list, whereas Community Engagement and Education and Collaborative Goal Setting are seen as the least impactful, with RIIs of 0.315 and 0.150, respectively.

For the classification of these strategies, the RII classification has been used based on Buertey et al. (2024) (Table 2).

Table 2: RII classification

RII Values	Importance Level
$0.90 \leq RII \leq 1$	Strongly Important
$0.75 \leq RII \leq 0.89$	Very Important
$0.60 \leq RII \leq 0.74$	Important
$0.45 \leq RII \leq 0.59$	Moderately Important
$0.30 \leq RII \leq 0.44$	Unimportant
$0.15 \leq RII \leq 0.29$	Very Unimportant
$0 \leq RII \leq 0.14$	Strongly Unimportant

The ranking of energy management strategies, according to the Relative Importance Index (RII) classification, illustrates the impact of technical advancements and organisational preferences on energy efficiency and conservation. AI and Machine Learning Based Predictive Control (0.892), Automation and Smart Controls (0.813), and Smart Metering and Monitoring Systems (0.758) are classified as "Very Important." These tactics are esteemed for embodying innovative, data driven methodologies that facilitate real-time energy optimisation, problem identification, and predictive maintenance. The incorporation of AI facilitates adaptive and anticipatory control systems, minimising energy waste and improving operational efficiency. Automation and smart systems decrease human error and assure constant performance, while smart metering provides granular visibility into energy usage trends, which is crucial for informed decision making and accountability.

In the "Important" category, Incentive Based Programs (0.712), Energy Dashboards and Visualization Tools (0.654), and Employee Training Programs (0.623) are acknowledged for their supportive and enabling roles. Incentives are robust motivators that encourage compliance and involvement in energy saving measures. They integrate individual or departmental interests with organizational sustainability goals. Dashboards and visualization tools can make energy data more accessible and actionable, enabling transparency and fostering a culture of awareness. Meanwhile, employee training programs are crucial for strengthening internal capabilities, fostering responsible conduct, and assuring optimal use of the established systems and technology.

Strategies ranked as "Moderately Important", such as Performance Monitoring and Feedback Systems (0.588), Behavioural Nudges Through Apps and Notifications (0.550), Policy Enforcement (0.492), and Energy Conservation Agreements (0.450), demonstrate attempts to support long-term engagement and compliance. These strategies are regarded

as somewhat effective because their effectiveness frequently depends on consistent implementation, user responsiveness, and cultural factors. For instance, feedback methods can improve performance only if users are motivated to act on the data. Similarly, behavioural nudges rely on psychological triggers, which may not consistently deliver sustained behaviour change. Policy enforcement and conservation agreements are crucial for formal accountability but may be regarded as top-down measures with limited flexibility or intrinsic incentive.

In the "Unimportant" category, Social Recognition Programs (0.385) and Community Engagement and Education (0.315) are considered to have less influence on energy results in business environments. This may be owing to the indirect nature of their impact, since they generally try to shift cultural norms or public awareness rather than offer instant, verifiable benefits. Their effectiveness may also be lessened in corporate organisations where quantifiable goals and returns on investment are stressed.

Finally, Collaborative Goal Setting (0.150) is classed as "Very Unimportant", probably because it demands significant work and coordination across departments, frequently without quick or evident energy savings. In practice, collaborative initiatives can confront obstacles linked to conflicting priorities, lack of engagement, or ambiguous accountability, making them less attractive compared to more direct or automated treatments.

Overall, this classification demonstrates a strong preference for technologically advanced, results oriented techniques that offer measurable and scalable energy reductions. It also emphasises a weaker emphasis on softer, community based, or participatory strategies, presumably due to their perceived lower impact and longer deadlines for effect.

Table 3: Classification on strategies

Classification	Strategies	RII
Very Important	AI and Machine Learning Based Predictive Control	0.892
	Automation and Smart Controls	0.813
	Smart Metering and Monitoring Systems	0.758
Important	Incentive based programs	0.712
	Energy Dashboards and Visualization Tools	0.654
	Employee training programs	0.623
Moderately Important	Performance monitoring and feedback systems	0.588
	Behavioural Nudges Through Apps and Notifications	0.550
	Policy Enforcement	0.492
	Energy Conservation Agreements	0.450
Unimportant	Social Recognition Programs	0.385
	Community Engagement and Education	0.315
Very Unimportant	Collaborative Goal Setting	0.150

5. DISCUSSION

This study's findings indicate an apparent trend in the apparel manufacturing sector towards the adoption of technologically advanced energy behaviour management measures. Amongst the thirteen techniques assessed, AI and Machine Learning Based Predictive Control obtained the highest Relative Importance Index (RII), closely followed by Automation and Smart Controls, as well as Smart Metering and Monitoring Systems. This pattern highlights a distinct industrial inclination towards data driven, real-time, and precision focused interventions capable of producing quantifiable results with less human involvement.

These top ranked techniques not only offer exceptional scalability but also align with the expanding digitalization trends in manufacturing. The strong RII values reflect credibility in these systems' ability to forecast consumption patterns, discover inefficiencies, and self-correct processes without the need for considerable user input. The introduction of such smart devices helps bridge the "energy performance gap" by decreasing the mismatch between expected and actual energy consumption levels, a recurrent challenge in energy saving programs.

Managerial and motivational initiatives such as Incentive Based Programs, Energy Dashboards, and Employee Training Programs also obtained significant attention, falling inside the "Important" category. These methods are crucial facilitators that promote technological interventions by encouraging awareness, engagement, and accountability among employees. Incentive schemes aim to integrate individual behaviours with organizational sustainability objectives, therefore improving the adoption and continued usage of new technology.

Conversely, methods relying on legal and social frameworks, including Policy Enforcement, Community Engagement, and Collaborative Goal Setting, turned out substantially lower. This trend reflects the corporate sector's preference for bottom line-oriented solutions over regulatory or socially motivated initiatives, which may be regarded as slower or less directly influential. Particularly, Collaborative Goal Setting being ranked as "Very Unimportant" shows that techniques involving substantial coordination and abstract results are commonly deprioritized in fast paced industrial environments.

Interestingly, behavioural and psychological methods like Behavioural Nudges and Recognition Programs also obtained low to moderate relevance ratings. This may reflect the problem of maintaining long-term involvement in behaviourally driven interventions without constant reward, monitoring, or integration with technology. The effectiveness of these tactics may also be context dependent, necessitating cultural transformations and leadership commitment that are sometimes difficult to maintain in changing manufacturing environments.

These observations emphasize the requirement of a hybrid approach that utilizes the precision and efficiency of sophisticated technologies while embedding behavioural and organizational enables them to ensure lasting impact. Despite the lower rankings of social and behavioural interventions, their synergistic integration with technological solutions may be vital for generating deeper and more sustainable improvements in energy use behaviour.

6. CONCLUSION

The paper offers a detailed investigation of energy behaviour control strategies within the apparel manufacturing sector, offering empirical evidence of their relative effectiveness through expert validation and Relative Importance Index (RII) analysis. The results suggest a strong industry preference for technologically driven initiatives, especially AI and machine learning based predictive control, automation, and smart metering systems. These solutions are prized for their capacity to deliver real-time, adaptive, and scalable energy optimizations that decrease waste and meet sustainability targets.

While managerial tactics such as training programs, incentive mechanisms, and performance monitoring have notable importance, they serve primarily as facilitators for the more impactful technical initiatives. Conversely, legal and social tactics, though potentially valuable, are sometimes deprioritized due to perceived complexity, slower return on investment, or mismatch with corporate priorities.

A critical recommendation resulting from this research is the adoption of a quantitative framework, one that mixes high impact technologies with structured behavioural and organizational components. Such a hybrid strategy targets not only operational efficiency but also the human components of energy use, delivering more robust and sustainable outcomes.

For governments and business leaders, these findings give a realistic roadmap to identify actions that balance cost effectiveness with long-term sustainability. Future studies might further explore the contextual factors driving the adoption of lower ranked methods, particularly in apparel, and analyse the long-term implications of integrated behavioural and technical solutions.

APPLICABILITY OF ARTIFICIAL INTELLIGENCE MODELS FOR SELECTION OF ADR METHODS TO THE SETTLEMENT OF CONTRACTOR-RELATED VARIATION DISPUTES IN BUILDING CONSTRUCTION PROJECTS IN SRI LANKA

Y.M.W.H.M.R.R.L.J.B. Kiridana[1] and M.D.T.E. Abenayake[2]

ABSTRACT

Construction disputes in Sri Lanka are highly technical in nature and differ significantly from general commercial disputes, necessitating fast and cost-effective resolution methods. Due to the drawbacks of litigation such as high cost, delays, and complexity, Alternative Dispute Resolution (ADR) methods have become increasingly important, offering advantages like speed, affordability, fairness, simplicity, flexibility, confidentiality, and minimal delays. In building construction projects, variations are common and often lead to disputes, with contractor-related variation disputes being particularly prevalent and impactful. Effective resolution of these disputes is essential for successful project completion. This research aims to propose a guideline that utilizes Artificial Intelligence (AI), including machine learning and deep learning techniques, to select the most suitable ADR method for settling contractor-related variation disputes in building construction projects in Sri Lanka. The study adopted a qualitative approach, conducting expert interviews with ten professionals selected through purposive sampling, all of whom had experience in ADR and construction variations. Data were analysed using code-based content analysis to identify appropriate ADR methods. The research findings led to the development of a guideline integrating AI tools to support decision-making in ADR method selection. This guideline provides valuable insights for industry practitioners, enabling more efficient and effective resolution of contractor-related variation disputes within Sri Lanka's building construction sector.

Keywords: *ADR Methods, Artificial Intelligence, Construction Industry, Contractor-Related Variation Dispute*

1. INTRODUCTION

The construction industry is one of the major industries which plays a vital role in the economy of any country (Illankoon et al., 2019). It has become more competitive and

[1] Graduate, Department of Building Economics, University of Moratuwa, Sri Lanka, kiridanaymwhmrrljb.19@uom.lk
[2] Senior Lecturer, Department of Building Economics, University of Moratuwa, Sri Lanka, mabeynayake@uom.lk

complex due to the increasing demands of employers and the global economic downturn (Farooqui et al., 2022). Consequently, variations are inevitable in those building construction projects, and it may escalate up to variation disputes (Perera et al., 2019). Cakmak and Cakmak (2014) described that contractor-related variation disputes are distinctive among variation disputes and, consequently, effective settlement procedures of contractor-related variation disputes are valuable to the successful completion of the building construction project. If the resolution of contractor-related variation raised disputes not focused properly, the proper sequence of the project may often be lost (Cheung et al., 2002) Various types of ADR methods can be used to resolve various building construction related disputes. The previous researchers have highlighted only the common disputes in building construction. According to this research, endeavour to establish a strategic guideline to settlement of contractor related variation raised disputes by using ADR methods. A detailed study to investigate the contractor-related variation disputes and how Alternative Dispute Resolution methods can apply for those disputes in the context of Sri Lankan building construction projects has not been done yet. Since the contractor-related variation disputes in the Sri Lankan building construction projects are different from other countries, carrying out a study to provide guideline to settlement of contractor related variation disputes by using ADR in building construction industry in Sri Lanka will be very important to the success of future construction industry in Sri Lanka.

Today, more than ever, it is clear that claims and disputes in the construction industry have become endemic, particularly those resulting from variations. Furthermore, Latham (1994) revealed that, one of the key issues in the building construction industry was variation and its impact on productivity. Similarly, variations are a key source of delays and cost overruns in building projects, and they are the source of many conflicts in construction contracts. In practice, the time and cost impact on the project is a contested topic when valuing a variation (Mustapha et al., 2018). According to Asamaoh and Offei-Nyako (2013), variations in the construction process at all stages have an impact on project administration. Time overrun and cost overrun are revealed as the leading effects of variation order (Asamaoh & Offei-Nyako, 2013). Furthermore Keane et al. (2010) also identified cost overrun, time overrun and contract disagreements between parties in contract are major impacts of variation. Arain and Pheng (2006) summarized the impacts of variations to building construction projects as follows: rising the project cost, need of hiring new professionals, procurement delay, increase in overhead expenses, and payment delays, quality reduction, productivity reduction, demolition and reworks, logistics delays, additional payments for contractor, conflicts among professionals and delay in the completion schedule.

Integrating Artificial Intelligence (AI) into the ADR process can improve the selection and application of resolution methods by providing data-driven insights, reducing time and costs, and enhancing decision-making. AI can analyse project data like contracts and designs to identify potential disputes early on. Using machine learning, AI can recommend the most suitable ADR method based on the nature of the dispute and its financial impact. AI can also streamline communication by automating document exchanges, speeding up negotiations, and ensuring transparency. Additionally, AI platforms can provide real-time insights, helping make better decisions during dispute resolution (Goh & Zhang, 2020). By using AI, the dispute resolution process becomes

faster, more accurate, and cost-effective, improving overall efficiency in Sri Lanka's construction sector.

2. METHODOLOGY

This study employed a qualitative research methodology combined with the development of Artificial Intelligence (AI) models to explore the applicability of AI in selecting appropriate Alternative Dispute Resolution (ADR) methods for contractor-related variation disputes in building construction projects in Sri Lanka. The research began with an in-depth literature review was conducted to critically examine existing ADR practices in the Sri Lankan construction context. This was essential to understand the local legal, procedural, and cultural aspects of dispute resolution, identify limitations in current methods, and ensure that any proposed AI application would be contextually relevant and practically viable. Moreover, the review helped define the research problem, identify knowledge gaps, and design the data collection framework. This review helped define the research problem and design the data collection framework.

To gather context-specific insights, semi-structured interviews were conducted with a purposively selected group of industry professionals, including project managers, contract administrators, dispute resolution experts, and consultants. The experts were selected based on their substantial professional experience, each having a minimum of 10 years in the Sri Lankan construction industry with direct involvement in managing contractor-related variations and dispute resolution. Inclusion criteria required that participants had (1) practical experience handling building construction projects under standard forms of contract, (2) prior involvement in variation-related disputes as a contracting party, consultant, or neutral third party, and (3) familiarity with at least one form of ADR method (e.g., adjudication, mediation, or arbitration). This ensured that their perspectives were grounded in both contractual and dispute resolution practice. A total of 10 experts, comprising 3 project managers, 2 contract administrators, 3 dispute resolution practitioners (including arbitrators and adjudicators), and 2 senior consultants, were interviewed. The sample size was determined based on the principle of data saturation, where additional interviews no longer yielded new themes or insights, and was considered sufficient to capture diverse yet deeply informed professional perspectives. The interviews focused on collecting qualitative data regarding the common causes and impacts of contractor-related variations, existing ADR practices, challenges in current dispute resolution processes, and key factors influencing the selection of ADR methods. Furthermore, participants were asked to reflect on the potential role of AI in enhancing ADR decision-making. While it was evident from the interviews that AI is not currently applied in real-world ADR processes within the local context, the insights obtained were systematically analysed and later used to identify relevant decision variables, which formed the basis for developing and training AI models for ADR method selection.

Following data collection, the interview responses were transcribed and analysed manually using thematic analysis. Key variables, decision factors, and common patterns were extracted and structured. These refined data points were then used as input to develop and train AI models aimed at predicting or recommending suitable ADR methods for specific dispute scenarios. Thus, although the study is grounded in qualitative research, it also incorporates a data-driven component by utilizing expert-derived knowledge to simulate the potential of AI-assisted decision-making tools.

This integrated methodological approach combining qualitative inquiry with AI model training allowed for both a deep understanding of industry challenges and a forward-looking evaluation of how AI could enhance dispute resolution processes in Sri Lanka's construction sector, despite its current lack of practical adoption.

3. DATA ANALYSIS

3.1 CAUSES OF DISPUTES ON VARIATIONS IN BUILDING CONSTRUCTION PROJECTS IN SRI LANKA

Various research have been conducted by the researchers along the different types of variation disputes (Bello & Saka, 2017). However, according to Keane et al. (2010), the most effective way to classify variation disputes is to classify them according to the cause. The following Table 1 presents the classification and related causes of variation disputes.

Table 1: Classification of variation disputes and causes

Client-related	Consultant-related
Change of plans or scope	Change in design
Insufficient planning at the project definition stage	Errors and omissions
Owners' financial problems	Poor coordination
Inadequate project objectives	Technology change
Replacement of materials/procedures	Value engineering
Impediment of prompt decision-making process	Conflicts among contract documents
Change in specifications by owner	Design complexity
Lack of involvement of the owner in design phase	Poor working drawing details
	Change in specifications

Cakmak and Cakmak (2014) described that contractor-related variation disputes are distinctive among variation disputes and consequently, effective settlement procedures of contractor-related variations disputes are valuable to the successful completion of the building construction project.

3.1.1 Settlement of Disputes through ADR Methods

According to the above mechanism both parties were responsible for resolving their own problems due to its voluntary character (Wimalachndra, 2007). This old system of ADR procedures encouraged peace and harmony, facilitated economic growth at the village level, and promoted social stability by bringing people together (Abeynayake, 2015). According to Abeynayake (2015) different ADR methods have been identified and utilized by stakeholders in the construction and commercial sectors in Sri Lanka at the modern era. In the construction industry, negotiation, mediation, conciliation, adjudication, and arbitration are known as widely used ADR methods (Abeynayake & Weddikkara, 2012).

3.1.2 Negotiation

Negotiation occurs whenever people discuss or share ideas in order to define or redefine the terms and conditions of their relationship. Further negotiation is a voluntary and usually informal procedure in which participants highlight areas of concern, examine options for resolving the problems, and seek a mutually acceptable solution to the issues (Abeynayake, 2015).

3.1.3 Mediation

Mediation is a collaborative, cooperative dispute resolution method in which the parties maintain influence over the outcome. Moreover, a systematic settlement of negotiation assisted by a neutral third party with no decision-making power is known as mediation (Kiridana et al., 2024). Mediation is a confidential process in which a neutral third party known as a mediator assists the parties in discussing and attempting to settle their disputes and consequently, the mediator has no authority to make a decision on behalf of the parties.

3.1.4 Conciliation

Conciliation is a procedure in which the parties to a dispute identify the disputed issues, develop options, consider alternatives, and attempt to achieve an agreement with the help of a neutral third party selected by the parties (Soorige & Abeynayake, 2015). Moreover, identified that, conciliation is a method of resolving disputes in which both parties agree to deploy a conciliator to help them resolve their issues and a third person successfully brings opponents together in conciliation.

3.1.5 Adjudication

Adjudication is a means of referring issues to a neutral third party for a decision that is only binding on the parties until the dispute is settled through arbitration or litigation). Abeynayake and Wedikkara (2013) revealed that, parties agree to nominate an adjudicator known as the Dispute Adjudication Board (DAB) or a single adjudicator at the start of the contract and the adjudicator is supposed to perform as an independent expert rather than an arbitrator. As a result, it is critical that the adjudicator be a person who is competent to interpret technical and contractual problems Abeynayake and Wedikkara (2013) revealed that, there is no such statutory recognition for adjudication methods in Sri Lanka, therefore the adjudicator's award has no legal standing. It is carried out in accordance with the CIDA Federation Internationale Des Ingenieurs-Counseils (FIDIC) conditions of contract, and consequently, unless the parties agree to enforce the award, the adjudicator's decision is not legally enforceable (Abeynayake & Weddikkara, 2013).

3.1.6 Arbitration

If a dispute cannot be settled amicably through mediation or adjudication, the case will be referred to an arbitrator for a binding decision (Kiridana et al., 2024). This is generally the forward methodology, and it incorporates the formal recognition of opposing viewpoints and issues. Moreover, according to Cheung et al. (2002), the most popular way for resolving construction disputes is arbitration, and most construction contracts have arbitration clauses that require the parties to refer any disagreements to arbitration. Abeynayake and Weddikkara (2013) identified that, an arbitral tribunal is supposed to act reasonably and impartially, as well as to follow procedures that minimize unnecessary

delays and costs. Moreover, arbitration, according to the American Institute of Architects, has been firmly established as a preferred way of private construction dispute resolution for many years. According to Stephenson (2018), arbitration is a legally binding process in which two or more parties agree that a dispute or potential dispute between them will be resolved by one or more unbiased persons in a judicial manner based on evidence presented before such person or group of people for a decision, and the decision is referred to as the award (Stephenson, 2018).

Analysis of the interview data revealed a consistent theme across all participants: the selection of the most suitable ADR method for a given dispute depends heavily on the dispute's nature, complexity, and characteristics. This conclusion was reached through thematic coding of the qualitative responses, where all 10 respondents independently highlighted that no single ADR method is universally applicable to every situation. For example, six experts emphasised that negotiation or mediation is often more effective for less complex disputes involving relationship-sensitive issues, while four experts stressed that adjudication or arbitration becomes necessary in technically complex disputes or where contractual interpretation is contested. Several respondents further noted that disputes involving high monetary values, multiple stakeholders, or cross-contractual claims often require more formal ADR mechanisms due to evidentiary and enforcement considerations. This recurring observation was coded under themes such as "ADR method selection factors," "complexity-based approach," and "dispute-specific tailoring," all of which appeared in every transcript. The universal occurrence of these themes across the sample provided the basis for the conclusion in Topic 6 that *all respondents agreed* on the situational nature of ADR method selection.

4. IMPORTANCE OF ADR METHODS FOR SETTLEMENT OF CONTRACTOR-RELATED VARIATION DISPUTES IN BUILDING CONSTRUCTION PROJECTS

When planning a construction project, the cost from start to finish seems to be of great importance, but variations have a significant impact on project cost overruns (Ranasinghe, 2014). In a construction project, the need to make changes is a practical reality (Keane et al., 2020). Even the most planned projects may necessitate changes due to various factors (Arain & Pheng, 2006). Variations orders are mostly responsible for cost and time overruns in building projects, with variation orders accounting for 6-17 % of cost overruns in building projects. Assaf et al. (2019) have revealed that the most significant contributors to claims and disputes were variation orders related to new requirements from clients and injustices to the contractor in variation evaluation.

Gillie et al. (1991) revealed that the main objective of alternative dispute resolution (ADR) is to resolve disputes by having the support of a neutral third party. Abeynayake and Wedikkara (2013) stated that there are two ADR groups such as formal – binding and informal – non-binding methods, and also stated that, most predominant requirement to achieve successful ADR is to aspiration for the parties to inspect the possibility for settlement. Different ADR methods consist of different characteristics, and those ADR methods have various times and cost factors, hence, choosing the precious method is important for a better outcome (Illankoon et al., 2019). Gunasena (2010) stated that arbitration, adjudication, mediation, conciliation and negotiation are widely used, basic ADR methods which can be used to the resolution of variations related disputes. As a

result, ADR methods are appropriate for resolving contractor-related variation disputes in the building construction sector, and they can be a component in a successful project (Kumaraswamy, 1997). The potential of maintaining business relationships is high when using the ADR method and this feature is critical to the building construction industry (Jannadia et al., 2000).

Table 1 illustrates the classification of variation disputes based on their underlying causes, as outlined by Keane et al. (2010). This cause-based categorisation is useful in the Sri Lankan construction context because it allows disputes to be traced directly to the responsible party either the client or the consultant thereby enabling a more targeted resolution strategy. Client-related causes typically stem from changes in project scope, inadequate planning during the project definition stage, or financial constraints affecting the owner's ability to proceed with the work. In contrast, consultant-related causes often involve technical aspects such as design changes, errors or omissions in design documentation, or poor coordination between design disciplines. By understanding these specific causal categories, stakeholders can more effectively assess the risk of variations leading to disputes and select appropriate dispute resolution mechanisms tailored to the dispute's origin.

4.1 REVIEW THE USAGE OF ADR IN THE BUILDING CONSTRUCTION INDUSTRY IN SRI LANKA

The conclusion that the appropriate ADR method depends on the nature, complexity, and characteristics of the dispute was based on expert survey results. Respondents rated factors such as dispute complexity, nature, and contractor's financial stability as highly influential in ADR selection. Over 80% identified these as key considerations.

Additionally, open-ended responses emphasized that ADR should be chosen based on the specifics of each case.

4.2 ISSUES TOWARDS MEDIATION

Table 2: Issues towards mediation

Issue	Sources	References
Mediator's lack of technical competence	8	11
Issue regard to the enforceability, because of non-binding	7	10
Mediator is only facilitator and not giving any opinions or decisions	5	6
Mediation provision is not included in SBDs in Sri Lanka	3	3
No guarantee that settlement will be reached	3	3
Reluctance of government stakeholders to take responsibility for the problem	2	2

4.3 ISSUES TOWARDS CONCILIATION

Table 3: Issues towards conciliation

Issue	Sources	References
Issue regard to the enforceability, because of non-binding	8	10
No guarantee that settlement will be reached	5	6
Lack of adequate skills of the conciliator regarding construction issues	4	5
Conciliation provision is not included in SBDs in Sri Lanka	3	3
Strong-willed conciliator can exercise much control	2	2

Although the issues identified in Tables 2 and 3 such as the mediator's or conciliator's lack of technical competence, enforceability concerns, and absence of statutory provisions could indeed arise in other types of construction disputes, their inclusion in this study is specifically linked to variation-related disputes for two main reasons. First, during the interviews, participants were explicitly asked to reflect on their experiences with *contractor-related variation disputes* and to identify mediation- or conciliation-related challenges they had encountered in resolving such disputes. Therefore, while the nature of these issues is not unique to variation disputes, the context in which they were reported was exclusively variation-related cases. Second, variation disputes often involve complex technical evaluations, contract interpretation, and valuation matters; these characteristics make issues such as a mediator's or conciliator's technical competence, enforceability of agreements, and procedural limitations particularly critical. As a result, even though similar challenges could affect other disputes, the frequency and impact of these issues were found to be especially pronounced in the context of variation disputes in this study's dataset.

According to both literature and expert survey findings, several drawbacks of mediation and conciliation in the construction industry of Sri Lanka. Findings of the expert survey also proved that the construction industry in Sri Lanka always attempts to present their disputes to a third party who has a broad understanding of a field. That is the immediate reason why those are not popular in construction industry in Sri Lanka.

4.4 EFFECTIVE ADR METHODS FOR IDENTIFIED CONTRACTOR RELATED VARIATION DISPUTES

According to the literature review findings, ten causes of contractor-related variation disputes are identified. In the expert interview, respondents suggested their views and the most appropriate ADR method for identified disputes. Further, findings of the expert survey proved that many of the above causes are practical issues and common in the construction industry. However, for practical reasons, some of the facts identified in the literature were excluded by the experts. As an example, unavailability of equipment and unavailability of skills were excluded by the experts by citing reasons. Moreover, experts were explained that contractor have responsibility to use technically appropriate equipment to relevant works and contractor should have skilled personnel and all required workers to perform the tasks according to contract. Therefore, the findings of expert interview proved that the contractor is ultimately responsible for the variation disputes caused by unavailability of skills and unavailability of equipment. Therefore, finding

solutions by ADR methods is a waste of time for such issues. Table 4 illustrates the given appropriate ADR methods by respondents.

Table 4: Contractor related variation disputes and ADR solutions

Contractor related variation dispute	ADR solution
Lack of involvement in design	Negotiation
Contractor's financial difficulties	Adjudication
Desired profitability	Adjudication
Differing site conditions	Adjudication
Fast-track construction	Negotiation
Poor procurement process	Adjudication
Lack of communication	Adjudication
Consultant's lack of experience	Adjudication

5. ARTIFICIAL INTELLIGENCE MODELS FOR SELECTION OF ADR METHOD

AI techniques can significantly support the development of intelligent systems for selecting appropriate Alternative Dispute Resolution (ADR) methods in construction-related disputes. While the following algorithms are general-purpose in nature, they can be integrated into comprehensive decision-making models to enhance the accuracy and effectiveness of ADR selection. These techniques analyse factors such as dispute type, financial impact, project complexity, and historical outcomes to support data-driven decisions.

5.1 SUPPORT VECTOR MACHINES (SVM)

SVMs are effective in handling complex and nonlinear data relationships. When incorporated into a broader decision-support system, they can classify disputes based on key features and predict the most suitable ADR method (e.g., mediation, adjudication) by learning from historical dispute data.

5.2 ARTIFICIAL NEURAL NETWORKS (ANNS)

ANNs can process large volumes of structured data to identify patterns and correlations among dispute characteristics. Within an integrated model, ANNs can support ADR recommendation by analyzing inputs such as dispute causes, contract type, and financial scale.

5.3 K-NEAREST NEIGHBOURS (K-NN)

K-NN algorithms are useful for identifying past disputes similar to the current case. As part of a larger ADR recommendation framework, K-NN can suggest methods that were effective in similar historical cases (Goh & Zhang, 2020).

5.4 NATURAL LANGUAGE PROCESSING (NLP)

NLP techniques allow for the processing of unstructured textual data—such as emails, reports, and contracts—to extract relevant dispute indicators. These indicators can then serve as input features for machine learning models used in ADR method prediction

Random Forest Algorithm and Reinforcement Learning (RL). Random Forests enhance prediction reliability by aggregating the output of multiple decision trees. In combination with RL, which optimizes decisions through iterative feedback, these algorithms can form part of adaptive systems that improve ADR recommendations over time.

5.5 FUZZY LOGIC SYSTEMS

Fuzzy Logic systems are particularly suited for handling ambiguity and subjectivity in dispute characteristics. When used within hybrid decision models, they offer flexibility by applying fuzzy rules to determine the most appropriate ADR pathway (Goh & Zhang, 2020).

In summary, while these algorithms are not standalone ADR selection models, they provide critical computational capabilities that can be combined with domain expertise and structured methodologies to develop robust, intelligent ADR decision-support systems tailored to the construction industry.

6. GUIDELINE TO SETTLEMENT OF CONTRACTOR RELATED VARIATION DISPUTES BY USING ADR METHODS IN BUILDING SRI LANKA

Guideline to settlement of contractor related variation disputes by using ADR methods in building construction industry in Sri Lanka can be mentioned as follows.

Figure 1 presents a structured guideline for resolving contractor-related variation disputes in the Sri Lankan building construction industry. It integrates Alternative Dispute Resolution (ADR) mechanisms with a novel application of Artificial Intelligence (AI) to support informed, efficient decision-making. At the center of this guideline is a pretrained AI model designed to assist in the early assessment of the dispute.

The AI model is trained on historical dispute data, incorporating features such as dispute type, financial impact, project complexity, and behavioral patterns of involved parties. When a new dispute arises, the model analyzes these inputs to determine whether negotiation is likely to be effective as a first-line ADR method. This ensures that the decision to negotiate is not made solely based on subjective judgment but is supported by evidence from past cases with similar profiles.

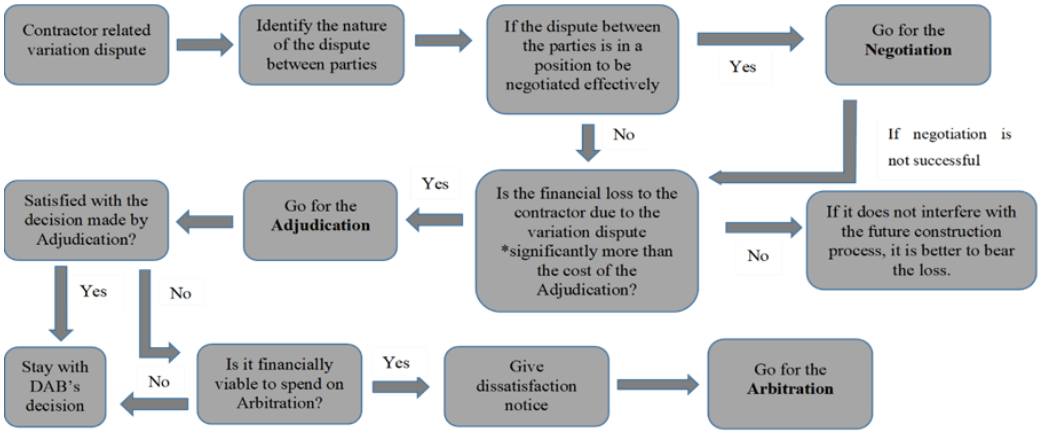

Figure 1: Guideline to settlement of contractor related variation disputes by using ADR in building construction industry in Sri Lanka

If the model predicts a high likelihood of successful negotiation, the process proceeds accordingly. However, if negotiation is deemed inappropriate or fails, the guideline shifts to a cost-benefit analysis stage, where the parties evaluate whether the potential financial loss warrants escalation to adjudication. If the loss justifies it, the dispute progresses to adjudication, and if the outcome remains unsatisfactory, it moves on to arbitration—ensuring that more formal and costly ADR methods are employed only when necessary.

This integration of a pretrained AI model with the ADR pathway ensures consistency, objectivity, and efficiency in the dispute resolution process. By aligning AI predictions with decision points in the guideline, the model functions as a decision-support tool, promoting faster, less adversarial outcomes and reflecting a proactive adoption of intelligent technologies in the construction dispute management framework.

7. CONCLUSION

Due to the industry's complexity, completing the project without making changes and adjustments to the construction process is practically impossible. Therefore, variations are inevitable in construction projects. According to the literature, Variation in construction refers to changes in design, quality, and quantity of work, as well as changes in the standard of materials or goods to be used in the work and the removal from site of any material that does not comply with the contract (Asamaoh & Offei-Nyako, 2013). Moreover, the literature has proven that variations can escalate into disputes, and then it can highly be influenced project cost, delays, conflicts, project quality, and issues in construction cost management in building construction projects. Accordingly, it is important to use a good settlement method to drive a project to successful completion. Consequently, in literature, variation disputes have been grouped into three categories for the contracting parties: client-related variations disputes, consultant-related variations disputes, and contractor-related variations disputes. In addition, a new group called "other variations disputes" has been created to represent non-party-related issues.

According to the classification derived from the literature survey, there are four main types of variation dispute categories. Among them, taking into account the specifics of contractor-related variation disputes as proven in the literature, it was taken to an expert interview. The purpose of these expert interviews was to discuss each of the above contractor-related variation disputes and select the ADR method that would lead to the most effective settlement for each type. However, in order to bring this work to a successful level, firstly got a basic understanding of the ADR methods used in Sri Lanka and their drawbacks from experts. As per the expert interviews, many of the facts mentioned in the literature were discussed, up to the point of proposing an effective ADR method, although some of the facts identified in the literature were excluded by the experts because of practical reasons. As an example, unavailability of equipment and unavailability of skills were excluded by the experts by giving reasons. However, with the exception of the two exclusions mentioned above, all the causes of contractor related variation disputes such as lack of involvement in design, Contractor’s financial difficulties, Desired profitability, differing site conditions, fast-track construction, Poor procurement process, Lack of communication and Consultant’s lack of experience have been accepted by experts and the most suitable ADR methods have been introduced for settle them. In developing this guideline, it was considered the expert reviews and according to that much attention was paid to selecting the ADR method with the most suitable cost range, depending on the financial value of the variation problem. Since

construction is an industry that must always be balanced with money, hence, every decision must be made in a way that does not lead to financial risk. Furthermore, considering the complexity and nature of the problem, attempts have been made to list ADR methods in an easy-to-use sequence, resolving issues that can be resolved through negotiations at an early stage and moving on to further methods only if they fail. Establishment of Negotiation and Mediation methods are suitable for settlement of disputes in the construction industry. Finally, to deviate this research to modern and smart Artificial Intelligence application is checked to select the most appropriate ADR method settlement of Dispute. It shows that the Artificial Intelligence concept can be applied where the AI models are trained using past project experience.

8. RECOMMENDATIONS

To further enhance the effectiveness and efficiency of the ADR methods in resolving contractor-related variation disputes, Artificial Intelligence (AI) can be employed as a highly effective tool. AI can be employed to examine large volumes of project data like contracts, designs, and communication records to identify trends and predict potential areas of dispute at an early stage of the project. AI can also provide real-time recommendations on the most appropriate ADR process with regard to the specifics of the controversy, such as economic considerations, nature of deviation, and parties involved. With the integration of AI into the ADR process, mediators and negotiators can obtain data-driven insights, which enable decision-making, minimize biases, and increase the likelihood of a successful resolution. Further, AI-based systems can automate bureaucratic tasks, such as document management and scheduling, so that the parties can focus on resolving the key issues properly. The adoption of AI into the ADR system can hence make the resolution of disputes more proactive, accurate, and inexpensive, ultimately paving the way to the smoother project completion of Sri Lankan constructions. Finally, as a whole, it can be concluded that the settlement of contractor-related variation disputes by using ADR in the building construction industry is not yet largely prevalent in the context of Sri Lanka. Though most Sri Lankan building contractors and construction sector possess the necessary basic knowledge and capacity to use ADR, an intercession from all related people and the government is necessary to effectively use and have faith and good practice ADR in the Sri Lankan context. The proposed guideline can be helpful to any level of the contractor to a better settlement of variation dispute by choosing the most appropriate ADR method by concerning the nature of the dispute.

APPLICABILITY OF LEAN MAINTENANCE PRACTICES TO MITIGATE MAINTENANCE MANAGEMENT ISSUES IN SRI LANKAN HIGH-RISE RESIDENTIAL BUILDINGS

U.H.M.S. Samaranayaka[1], U. Rathnayake[2] and A.S.W. Karunarathna[3]

ABSTRACT

Maintenance management (MM) is considered a critical function in residential buildings, ensuring longevity, safety, operational efficiency and cost-effectiveness. Compared to low-rise or mid-rise residential structures, high-rise residential buildings often face more complex and frequent maintenance-related issues due to their scale, building systems, and occupancy density. According to previous studies, implementing lean in maintenance is an effective strategy to improve maintenance efficiency. Thus, this study investigates the applicability of lean maintenance practices to mitigate such issues in Sri Lankan high-rise residential buildings and proposes suitable strategies for improvement. A qualitative case study approach was adopted, involving semi-structured interviews with maintenance personnel from four high-rise residential buildings in Colombo district. Additionally, the findings revealed that seven out of eight lean maintenance wastes prevailed in the selected cases. Further, three expert interviews were carried out to propose strategies to overcome the identified challenges in lean implementation. The findings of expert interviews revealed that the lack of lean knowledge and resistance to change in top management are the main challenges to implement lean maintenance in high-rise residential buildings in Sri Lanka. Further, experts proposed several key strategies for high-rise residential buildings, including encouraging lean certificates for maintenance supervisors, integrating feedback systems using QR codes or CMMS, visual dashboards, conducting lean awareness workshops, etc. The findings of this study are useful to address the existing MM issues and implement lean maintenance practices in high-rise residential buildings in Sri Lanka.

Keywords: *High-Rise Residential Buildings; Lean; Lean Maintenance; Maintenance Management; Strategies.*

1. INTRODUCTION

Maintenance management (MM) is a systematic process of planning, organizing, and evaluating maintenance activities and the associated costs (Khider & Hamza, 2022). Organizations consider maintenance as a critical requirement for providing a better built

[1] Engineering Executive, Teejay Lanka PLC, madhushika1218@gmail.com

[3] Lecturer, Department of Facilities Management, University of Moratuwa, Sri Lanka, sandunik@uom.lk

environment to occupants by ensuring assets and equipment are optimally functional (Mong et al., 2019).

MM is crucial in the housing industry to support human daily routines and improve the productivity of the activities in and around the residences (Au-Yong et el., 2019). In prior studies, it is mentioned that the maintenance issues faced by residents of high-rise residential buildings are mainly caused by inefficient maintenance management systems, insufficient regulations in maintenance management, and resident dissatisfaction with the service quality of building management because of the increasing demand (Amani et al., 2018). Through the implementation of lean concepts and procedures, lean thinking can be integrated into maintenance works and it can be applied to address challenges in MM while aligning maintenance with business objectives, thus maximizing revenues (Ghayebloo & Shahanaghi, 2010). According to Jasiulewicz-Kaczmarek and Saniuk (2018), Lean Maintenance (LM) aims to achieve the optimal level of equipment reliability while using a minimum of resources. In addition, maintenance performance can be enhanced by implementing LM tools (Mostafa et al., 2015).

However, there is a lack of empirical research on its application within the context of high-rise residential buildings in developing countries such as Sri Lanka. This gap is particularly critical given the increasing demand for high-rise housing and the complex challenges associated with managing such facilities. Therefore, this paper aims to investigate the potential for applying Lean Maintenance principles in high-rise residential buildings in Sri Lanka. Specifically, the study explores existing MM practices, identifies barriers to LM adoption, and recommends strategies for effective implementation. The paper begins with a literature review, followed by the research methodology, data analysis, key findings, and concludes with practical implications and future research directions.

2. LITERATURE REVIEW

2.1 COMMON MAINTENANCE MANAGEMENT ISSUES IN HIGH-RISE RESIDENTIAL BUILDINGS

MM is critical in high-rise residential buildings as it directly impacts the safety, functionality, and longevity of the building's systems and structures (Horner et al., 1997). Au-Yong et al. (2018) reported that poor MM performance in high-rise residences often arises from systematic inefficiencies, including the absence of maintenance standards, irregular preventive maintenance and poor service quality. According to Au-Yong et al. (2023), common MM issues include lack of awareness or cooperation of the residents, lack of preventive maintenance, unavailability of spare parts, etc. More recent findings by Au-Yong et al. (2023) highlighted specific challenges such as unqualified contractors, inadequate staff training, limited use of maintenance software, unclear job roles, and non-cooperative residents. According to De Silva et al. (2012), the lack of defined maintenance policies and reliance on reactive approaches increases such challenges. Although MM issues are prevalent in high-rise residential buildings in Sri Lanka, they have not been extensively explored; therefore, it is essential to address these issues through structured and proactive strategies (De Silva et al., 2012).

2.2 LEAN MAINTENANCE IN HIGH-RISE RESIDENTIAL BUILDINGS

The LM concept is based on lean manufacturing, which emphasizes reducing waste and increasing production efficiency (Bruun & Mefford, 2004). LM aims to increase overall equipment efficiency (OEE), decrease unnecessary downtimes and streamline operations by eliminating non-value-added activities (Womack & Jones, 1997). There are eight types of lean waste identified during maintenance which can negatively impact operational efficiency (Bhamu & Sangwan, 2016). While lean principles have been widely adopted in the manufacturing and industrial sectors to improve process efficiency and eliminate non-value-added activities, their application in residential building maintenance, especially in high-rise environments, is still underexplored (Womack & Jones, 1997).

Residential buildings show unique challenges that are not present in industrial operations, such as unpredictable tenant behaviour, varied building system usage patterns, shared responsibilities, and lack of centralized operational management (Au-Yong et al., 2018). These variations in context limit the direct transferability of traditional lean tools, which were initially intended for structured, repetitive industrial processes (Ghayebloo & Shahanaghi, 2010). Furthermore, the research indicates a lack of prior studies focusing on the integration of lean practices within the high-rise residential maintenance context in developing countries like Sri Lanka (De Silva et al., 2012). The majority of research focuses on Lean applications in manufacturing or on general maintenance strategies in commercial and public facilities, with little emphasis on adapting lean thinking to address the unique maintenance inefficiencies in high-rise residences (Au-Yong et al., 2023). However, Mostafa et al. (2015), stated that, in high-rise residential buildings with high complexity and maintenance demands, lean tools like as 5S, visual management, standardised work, and root cause analysis can assist in simplifying operations and decreasing delays caused by poor planning, unqualified employees, or a lack of preventive maintenance. Further, lean can be considered as the most flexible, easiest and low-cost solution for any buildings (Ahiakwo et al., 2012).

2.3 CHALLENGES IN IMPLEMENTING LEAN MAINTENANCE IN HIGH-RISE RESIDENTIAL BUILDINGS

De Silva et al. (2012), have established eight challenges of lean maintenance out of fifty-one maintainability causes associated with building maintenance in a study conducted in thirty high rise buildings in the Colombo district namely, 1) Architecture and design, 2) Service integration, 3) Materials and spare parts, 4) Construction quality, 5) Accessibility, 6) Structural and detailing, 7) Maintenance requirements, and 8) Maintenance management. Except for maintenance management, every other issue starts during a building's design and construction phases, making it difficult to deal with them during the operational stage (De Silva et al., 2012). According to Wood (2005), long-term and cost-effective strategies are not used in building maintenance, which makes it more challenging to apply lean principles and effective use resources. People are resistant to change because they feel more comfortable and safer being in the immediate environment and fear the consequences of change, which makes it challenging to implement lean maintenance in high-rise buildings (Asnan et al., 2015).

3. RESEARCH METHODOLOGY

This study aims to investigate the applicability of lean maintenance practices as a solution to mitigate the maintenance management issues in Sri Lankan high-rise residential buildings. As proven in the background and literature review, it is evident that MM in high-rise residential buildings has not been paid enough attention and can be improved by applying lean maintenance principles and tools. Therefore, MM practices in high-rise residential buildings in Sri Lanka were selected as the unit of analysis for this study. A comprehensive literature review was conducted to perceive theory-based knowledge regarding the concept of lean maintenance and identify the applications of lean maintenance in building maintenance.

Data collection for this study was carried out in two phases. Phase I involved a case study analysis, focusing on four high-rise residential buildings located in the Colombo District. These buildings, each exceeding 50 meters in height, were purposefully selected to generate comparable results relevant to the study. Further selection was narrowed down to four cases with a time limitation. From these buildings, eight participants were chosen for semi-structured interviews, representing a range of roles from managerial to technician level. All respondents had over five years of direct experience in maintenance operations.

The selection of four high-rise residential buildings was based on purposeful sampling to ensure relevance and data richness. These buildings were chosen as they represent typical residential high-rises in Sri Lanka facing common maintenance issues. Criteria included building height, residential function, being operational for over five years, and accessibility to maintenance data. In qualitative case study research, depth of insight is prioritized over quantity. A multiple-case design with as few as four well-documented cases can offer robust analytical generalization when each case is carefully selected based on theoretical and practical relevance. The four selected buildings provided a comprehensive dataset through interviews, observations, and document analysis, which allowed for meaningful cross-case comparisons.

The primary aim of the case studies was to identify common maintenance management (MM) issues, examine existing lean maintenance waste, and explore challenges in implementing lean maintenance practices in high-rise residential buildings. Given the exploratory nature of the study, a qualitative approach was deemed appropriate. Data collected from the interviews were analyzed using manual content analysis and cross-case analysis techniques to uncover key themes.

The profile of the selected high-rise residential buildings and the case study participants in this research are provided in Table 1 and Table 2 respectively.

Table 1: Profile of the selected cases

Case name	Description
Case A	A residential building which is 182 meters in height in Colombo
Case B	A residential building which is 240 meters in height in Colombo
Case C	A residential building which is 50 meters in height in Colombo
Case D	A residential building which is 126 meters in height in Colombo

Table 2:Profile of the respondents with experiences

Building	Code of respondents	Description	Years of experience
A	A1	Property Manager	10 years
	A2	Technician	More than 5 years
B	B1	Property Manager	10 years
	B2	Technician	5 years
C	C1	Property Manager	More than 5 years
	C2	Technician	More than 5 years
D	D1	Property Manager	10 years
	D2	Technician	More than 5 years

Expert interviews were conducted under Phase II of the data collection to suggest strategies to eliminate identified lean maintenance waste which then contributes to mitigating maintenance issues. Another purpose of the expert interviews is to suggest strategies to overcome challenges in implementing lean maintenance in high-rise residential buildings in Sri Lanka. Three specialists with experience in both lean and maintenance fields were chosen for the expert interviews. The experts were questioned through semi-structured interviews and revealing the gathered data from case studies securing confidentiality. The data gathered from expert interviews were analysed using a qualitative data analysis technique called template analysis. Table 3 presents a summary of the experts selected.

Table 3: Profile of the selected experts

Expert Respondents	Year of Experiences	Description
E1	10+ years	Senior Lecturer, Lean Consultant
E2	15 years	Certified Total Production System & Total Management System Practitioner (Grade IV) by a leading automobile manufacturer in Japan
E3	27+ years	Systems Consultant (KAIZEN, TQM, Japanese 5S, TPM, Japanese Management Practice)

4. FINDINGS AND DATA ANALYSIS

4.1 FINDINGS OF THE CASE STUDY

Data collection from case studies was executed based on a semi-structured interview guideline which mainly covered areas such as existence of MM issues, existence of lean maintenance wastes and challenges to implement lean maintenance. Existence of the following common MM issues were identified through the case studies.

Table 4:Responses on existing maintenance issues in selected cases

Common MM Issues	Case A		Case B		Case C		Case D		Total
	A1	A2	B1	B2	C1	C2	D1	D2	
Lack of Awareness or Cooperation of the residents	✓	✓	✓	✓	✓	✓	✓	✓	8/8
Unqualified Maintenance Contractors	✓		✓		✓		✓	✓	5/8
Lack of Maintenance Personnel Training and Motivation	✓				✓		✓		3/8
Budget Constraints					✓	✓	✓	✓	4/8
Lack of knowledge and Skills	✓		✓		✓		✓		4/8
Lack of staff and Specialists	✓		✓		✓	✓	✓		5/8
Lack of Maintenance Software Tools	✓		✓		✓		✓		4/8
Unclear Job Description or Department Structure	✓		✓		✓		✓		4/8
Failure of preventive maintenance	✓	✓	✓		✓		✓		5/8
Unavailability of Spare parts	✓		✓		✓		✓		4/8

Table 4 presents the summary of the respondents in selected cases regarding the existence of common maintenance issues in high-rise residential buildings. According to responses, each case has more than five maintenance issues.

4.1.1 Lack of Awareness or Cooperation of the Residents

As noticed in the interviews, residents' cooperation plays a crucial role in maintenance efficiency. All the respondents highlighted that lack of awareness or cooperation of residents is an issue in all four cases. Respondents C1 and D1 highlighted that delays often occur due to residents failing to report issues promptly. A1 further noted that ineffective communication between residents and maintenance staff leads to repeated visits for the same issue. Similarly, B1 explained that when residents are unaware of their responsibilities, such as reporting minor leaks or faults, small issues escalate into major repairs. Moreover, D2 stated that, by the time they get to a reported issue, it has already worsened because residents waited too long to inform them.

4.1.2 Unqualified Maintenance Contractors

In all four cases, respondents A1, B1, C1 and D1 mentioned that maintenance contractors are often hired based on cost rather than expertise. Respondent C1 observed that some contractors perform unnecessary repairs due to a lack of specialized training, which

increases operational costs. Respondent B1 highlighted that sometimes unqualified contractors often fail to diagnose the root causes of issues, leading to repetitive repairs.

4.1.3 Lack of Maintenance Personnel Training and Motivation

Training and motivation gaps were commonly mentioned by most of the respondents. Respondent D1 emphasized that some junior technicians lack formal training, making them inefficient in troubleshooting complex building systems. Respondent C1 added that due to poor career development opportunities, maintenance staff often feel demotivated, leading to suboptimal performance.

4.1.4 Budget Constraints

Financial limitations are commonly in all four cases. Respondent C1 mentioned that maintenance budgets are frequently cut due to financial constraints from building management committees, which delays crucial repairs. In addition, respondents C2 and D1 both agreed that budgetary restrictions also hinder the adoption of advanced maintenance technologies, reducing efficiency in the long run.

4.1.5 Lack of Knowledge and Skills

Respondents D1 and B1 both pointed out that maintenance personnel often lack updated technical knowledge, particularly in specialized systems such as HVAC, elevator maintenance, and fire safety. Further, respondent A1 also agreed with the above statements and suggested that regular technical training sessions could solve more problems in-house instead of relying on expensive external contractors.

4.1.6 Lack of Staff and Specialists

Both respondents A1 and B1 noted that many high-rise residential buildings face a shortage of skilled maintenance personnel, leading to increased workload for existing staff. Moreover, respondent C1 highlighted that specialist services, such as major electrical and plumbing repairs, frequently require outsourcing due to the unavailability of in-house experts, increasing overall maintenance costs and response times.

4.1.7 Lack of Maintenance Software Tools

Respondents A1, B1, and C1 noted that their buildings still rely on paper documents for tracking and recording maintenance tasks and information, which is leading to inefficiencies and data loss. Furthermore, A1 pointed out that they planned to include maintenance record process into a software in near future which needs high investment and staff training.

4.1.8 Unclear Job Description or Department Structure

All four respondents in four cases, A1, B1, C1 and D1, agreed that unclear job responsibilities cause inefficiencies in maintenance operations. However, all respondents stated that in their buildings, the occurrence of unclear job descriptions and department structure is limited.

4.1.9 Failure of Preventive Maintenance

As observed in the case studies, preventive maintenance strategies are implemented in all four buildings but often result in inefficiencies. Respondents A1 and B1 stated that excessive preventive maintenance is sometimes unproductive, as certain tasks are

performed without evaluating necessity. Further, respondent A2 argued that even preventive maintenance takes time it is essential to perform which cannot be skipped.

4.1.10 Unavailability of Spare parts

The unavailability of spare parts is a common issue identified among all four cases. Respondent A1 explained that they only keep spare parts which needed in their daily minor maintenance activities and all other major activities are outsourced, and the required spare parts will be provided by them.

4.2 The Relationship between Common Maintenance Issues and Existing Lean Maintenance Wastes

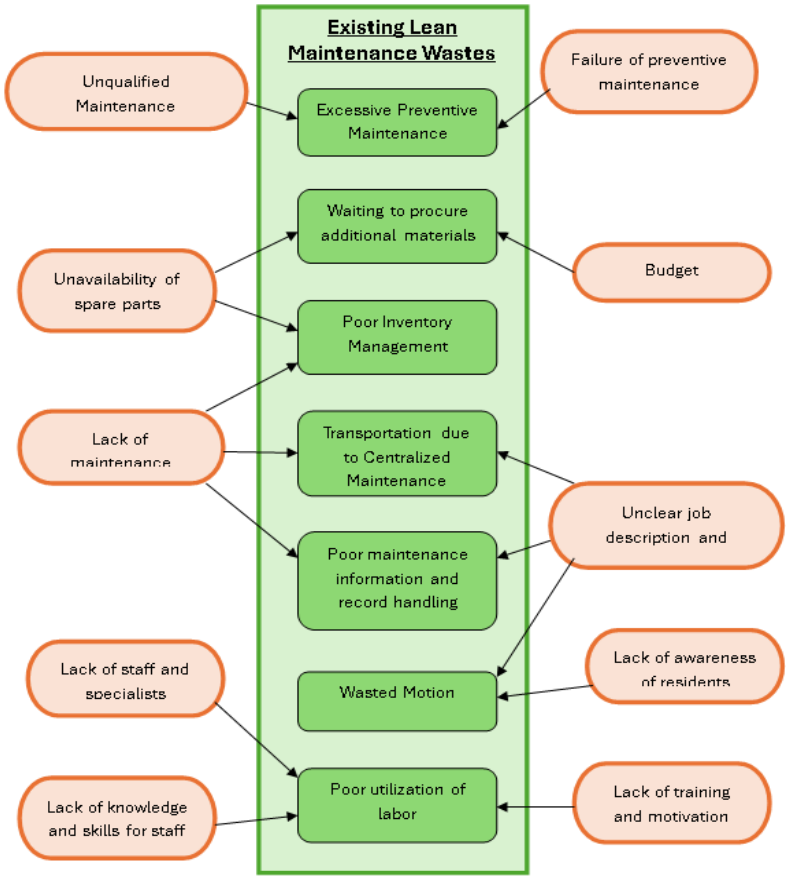

Figure1: Relationship between common maintenance issues and existing lean maintenance wastes

Figure 1 presents the relationship between the identified maintenance issues in the selected cases which are caused for the occurrence of identified existing lean maintenance waste. The indicated LM wastes in Figure 1 identified and confirmed through the conducted four case studies. Further, the relationship between these MM issues and LM wastes were identified with the discussion of experts who were involved in expert interviews.

4.3 Identification of Challenges in Implementing Lean Maintenance in High-Rise Residential Buildings in Sri Lanka

Challenges identified in the literature in implementing lean maintenance in high-rise buildings were discussed with the interviewees in four case studies to verify their

availability in the selected cases. The presented challenges were modified based on the interview findings and the list of challenges are shown in Table 5.

Table 5:Responses on challenges in implementing lean maintenance

Challenges	Case A		Case B		Case C		Case D		Total
	A1	A2	B1	B2	C1	C2	D1	D2	
Ineffective maintenance strategies	✓	✓	✓	✓	✓	✓	✓	✓	8/8
Lack of standards and regulations	✓	✓	✓	✓	✓	✓	✓	✓	8/8
Lack of policies	✓	✓	✓	✓	✓	✓	✓	✓	8/8
Lack of lean knowledge	✓	✓	✓	✓	✓	✓	✓	✓	8/8
Poor involvement of top management and resistant to change	✓		✓		✓	✓	✓	✓	6/8
Lack of technology usage	✓	✓	✓		✓		✓		5/8
Infirm feedback collecting mechanisms	✓		✓		✓		✓	✓	5/8

As Table 5 shows, all the respondents agreed that they face ineffective strategies, lack of standards, regulations, policies and knowledge of lean. Furthermore, poor involvement of top management, infirm feedback collecting mechanisms and lack of technology usage also prevail in all the selected cases. The following subsections present the explanation of the challenges shown in Table 5.

4.3.1 Ineffective Maintenance Strategies

All the respondents agreed that they follow preventive maintenance as their main maintenance strategy in their buildings. It was shown that only cases A, B and C have adopted to condition based maintenance up to a certain extend which is a preventive maintenance strategy that relies on the monitoring of assets or equipment to determine when maintenance work is necessary. But in case D they mentioned that, sometimes they follow corrective maintenance strategies with the preventive maintenance as well. It is evident that currently none of the cases has been fully adopted for any cost-effective maintenance strategy like condition-based maintenance. Therefore, it will be challenging to adopt lean with the traditional maintenance methods.

4.3.2 Lack of Standards and Regulations

All the respondents confirmed that currently, they do not follow any specific standard or regulation relating to maintenance. However, some of the respondents mentioned that in the Apartment Ownership Law there are certain rules regarding the maintenance. Further, respondent B1 stated that for the condominiums the governed law is Apartment Ownership Law, and, in that law, there are certain requirements regarding apartment maintenance like management council is only responsible for managing common areas and residents should manage and maintain the inside of their apartment units, etc. In addition to that, respondents in cases C and D also stated that they are not following any

standard or regulations related to maintenance. Therefore, it is evident that none of the cases are following or complying with standards or regulations relating to maintenance except the Apartment Ownership Law.

4.3.3 Lack of Lean Knowledge

All the respondents in four cases stated that they do not have knowledge regarding the lean concept and its applications. However, respondent A1 mentioned that even though she has learnt about lean in higher studies, she has not specifically come across lean maintenance before. Therefore, it is revealed that all the respondents do not know about lean. Thus, for the successful implementation of lean, it will be required to educate maintenance staff about lean concept, its principles and tools.

4.3.4 Lack of Policies

It was discovered that none of the cases has an explicit maintenance policy. All the respondents affirmed this. Respondent A1 stated that their plan is to shift from preventive maintenance to conditioned based maintenance. Respondent B1 also confirmed that they always aim to reduce maintenance costs and reduce breakdowns as much as possible, even though they do not have a policy. Respondents from cases C & D also stated that there is no maintenance policy. Therefore, it can be concluded that none of the cases have identified need for a maintenance policy.

4.3.5 Poor Involvement of Top Management and Resistant to Change

Six out of eight respondents identified top management's involvement in maintenance as a key obstacle to implementing lean maintenance strategies. Respondents from cases A, B and C mentioned that it is difficult to get the approval from top management for the new maintenance systems since they are resistant to change from the traditional maintenance methods due to high costs and unclear returns. For getting approval from top management, they require the estimated cost savings, but the maintenance staff does not track the cost of replacements or improvements, making it hard to prove financial benefits. Similarly, respondents D2 mentioned that top management does not fully understand the need for maintenance upgrades and remains hesitant due to uncertainty about potential benefits. Therefore, it is identified that resistant to change among the top management is the main challenge of lean implementation.

4.3.6 Lack of Technology Usage

The respondents from all cases confirmed that no advanced technology is currently used for maintenance, only use MS Excel and no dedicated software. Respondent A1 stated that they plan to incorporate maintenance activities into resident complaint management software and respondent B1 emphasized that they plan to implement a helpdesk system to track maintenance activities. Moreover, all the respondents mentioned that having a centralized system for tracking maintenance tasks and spare parts availability would be much easier to reduce delays and ensure preventive maintenance.

4.3.7 Infirm Feedback Collecting Mechanism

Five out of eight respondents mentioned that there is no formal mechanism for collecting and recording feedback on attended maintenance complaints. Respondent B1 also stated that they do not have proper feedback collection process, but they plan to include that feedback mechanism also in the proposed helpdesk system. The responses from respondents A1, B1, C1, D1, and D2 indicate that the feedback collection process in these

buildings is entirely informal and lacks consistency, which makes it difficult to assess customer value and service quality. Therefore, it is important to implement such a computerized mechanism to collect and review feedback from end-users for improving maintenance operations and enhancing customer satisfaction.

4.4 STRATEGIES TO OVERCOME CHALLENGES IN IMPLEMENTING LEAN MAINTENANCE IN HIGH-RISE RESIDENTIAL BUILDINGS IN SRI LANKA

4.4.1 Strategies to Overcome Poor Involvement of Top Management and Resistance to Change

All the experts suggested conducting awareness programmes for the management regarding lean as the main strategy to overcome poor involvement of top management as most of the organizations do not practices lean tools and have no proper knowledge about lean. Further, they emphasized the importance of providing financial information such as, implementing costs and expected ROI, to help top management make informed decisions. Additionally, they suggested introducing low-cost or no-cost lean suggestions as pilot projects to encourage top management's involvement in capital intensive maintenance projects.

4.4.2 Strategies to Overcome Ineffective Strategies

According to respondent E1, it is important to have brainstorming sessions in between the maintenance staff and stakeholders which help to fine-tune the existing strategies and practices. Moreover, conducting brainstorming sessions with people in the work floor give effective results because they have the best experience in every perspective. In addition to that, setting KPIs are essential to make strategies effective.

4.4.3 Strategies to Overcome Infirm Feedback Collecting Mechanism

All the respondents agreed that it is essential to implement computerized feedback collecting software to collect feedback from residents. Further, respondent E2 added that feedback is very important to improve the current state of the maintenance works. Therefore, it would be easy for them to have a computerized system to collect feedback. Similarly, respondent E3 also stated that the best option is to streamline feedback collection system, in that way it is easy to trace the jobs requested, actions taken and to give feedback on the job performed. Therefore, it is confirmed that implementing computerized feedback collection system is essential.

4.4.4 Strategies to Overcome Lack of Lean Knowledge

All the experts unanimously agreed that to increase awareness of lean among maintenance staff is important and for that conducting awareness programs are crucial. Furthermore, Respondent E3 added that practical knowledge in implementing lean can be gained by engaging in lean professional qualifications for instance lean six sigma professional qualifications. Similarly, E1 also mentioned that it would be beneficial to engage with lean experts.

4.4.5 Strategies to Overcome Lack of Policies

Lack of proper policies will impact the proper implementation of lean maintenance. To overcome this challenge, both E2 and E3 experts mentioned that it is essential to establish proper maintenance policies, and those policies need to be drafted integrating SMART such as, specific, measurable, achievable, relevant, and timely objectives. Furthermore,

link the established policies with incentives, which means rewarding teams for reducing downtime or energy waste in the building systems

4.4.6 Strategies to Overcome Lack of Standards and Regulations

Lack of proper standards and regulations also will impact negatively when implementing lean maintenance in any organization. When addressing this challenge experts suggested that align with industry benchmarks such as, adopt ISO 41001 standard for facility management or NFPA codes for fire safety compliance are important. Similarly, E3 added that if there are no local standards and regulations relating to maintenance it is essential to comply with other global standards available with appropriate modification. Furthermore, developing customized SOPs can also be identified as a strategy.

4.4.7 Strategies to Overcome Lack of Technology Usage

In present, technology is a key aspect in any organization, which improves the operational efficiency and saves time. To overcome this challenge, experts suggested that application of Industry 4.0 and the adaptation of information technology advancements in maintenance sector is essential.

5. DISCUSSION

This study investigates the suitability of LM approaches for addressing MM challenges in Sri Lankan high-rise residential buildings. The findings demonstrated a clear relationship between LM wastes and common MM issues in the local residential context, confirming the importance of applying lean strategies to this sector. Across all four case studies, recurring issues such as excessive preventative maintenance, high wait times, poor inventory management, and personnel underutilisation were directly associated with recognised Lean maintenance wastes. These inefficiencies restrict building performance and highlight the necessity for structured, proactive approaches. For example, excessive PM was prevalent within all four cases, typically due to rigid OEM schedules and unprepared application of standard checklists. This supports Mostafa et al. (2015), who emphasized that over-maintenance could result in waste if not tailored to actual asset conditions. Similarly, transportation waste due to centralised maintenance hubs and waiting for spare parts was evident in the cases investigated, echoing Lean theory which emphasis on reducing unnecessary movements and delays (Womack & Jones, 1997). These issues were worsened by a limited use of digital tools, poor inventory control, and fragmented job responsibilities, which decrease system reliability and increase costs.

All cases indicated a lack of Lean awareness, the absence of maintenance policies, and limited involvement from top management, demonstrating structural barriers to implementing Lean. The consistency of these findings across multiple buildings suggested systemic weaknesses rather than isolated operational failures. The lack of computerised systems or digital tracking methods limited real-time monitoring, resulting in inadequately documented procedures and reactive maintenance behaviour. This finding supports Jasiulewicz-Kaczmarek and Saniuk (2018), who identified digitalization as critical to Lean integration. Notably, unqualified contractors and lack of skilled labour resulted in more rework, longer downtimes, and high costs, which is consistent with prior findings by Au-Yong et al. (2023), on MM inefficiencies in high-rise residential contexts. The reported absence of formal standards, such as ISO 41001, emphasises the need for regulatory support to enable Lean adoption in residential settings.

Expert interviews validated these findings and suggested practical Lean strategies. For example, to address excessive PM, experts proposed switching to condition-based maintenance and autonomous maintenance. These approaches, while frequently used in industry, are novel in the residential sector and show potential for increasing system uptime and decreasing resource waste. Similarly, the idea of using mobile carts and decentralised hubs to reduce technician travel time aligns with Lean's philosophy of minimising motion waste. Additionally, experts emphasised the importance of computerised feedback systems, visual dashboards, and Industry 4.0 technologies to enhance decision-making and transparency. These solutions could help minimise feedback gaps and increase maintenance teams' responsiveness, which were previously restricted by paper-based processes.

Overall, the study shows that Lean Maintenance can be successfully applied to the residential high-rise context when supported by simple technologies, adequate training, and leadership commitment. These findings contribute to developing both theory and practice by providing a context-specific approach for improving maintenance performance in the built environment.

6. CONCLUSION

This study examined the applicability of LM practices in mitigating MM issues in Sri Lankan high-rise residential buildings. Through case studies, the research identified seven out of eight lean wastes prevalent in the selected buildings. Common MM issues were found to correspond with known lean inefficiencies. Further, key challenges are lack of lean knowledge and limited support from top management factors that hinder the lean adoption. Expert interviews validated these findings and proposed suitable strategies including, lean awareness programs, feedback systems using digital tools and aligning maintenance policies with SMART objectives. This study provides practical insights for facility managers and decision makers, highlighting feasible strategies to improve building maintenance efficiency. Thus, this study emphasizes the applicability of lean maintenance practices in mitigating maintenance issues in Sri Lankan high-rise residential buildings.

ARTIFICIAL INTELLIGENCE DRIVEN SYSTEMS FOR ENHANCING WORKER SAFETY MONITORING IN CONSTRUCTION ENVIRONMENTS: A COMPREHENSIVE REVIEW

J.A.U.S. Jayakody[1] and P.R.H.N.G. Thilakarathne[2]

ABSTRACT

The construction industry remains one of the most hazardous sectors globally, largely due to inefficiencies, high operational costs, and delayed risk detection associated with traditional safety procedures. This comprehensive review synthesizes findings from 88 peer-reviewed studies published between 2017 and 2025 to evaluate the potential of Artificial Intelligence (AI)-driven systems in enhancing worker safety. The review addresses three primary objectives: (1) evaluating the effectiveness of AI technologies in improving safety monitoring, (2) examining regional variations in AI adoption and their influence on safety outcomes, and (3) identifying key challenges related to implementation, scalability, and ethical considerations. The analysis reveals that AI technologies significantly contribute to improved safety outcomes. For instance, drone-based inspections reduce assessment times from several days to approximately 1.5 hours with high accuracy; computer vision systems detect personal protective equipment (PPE) violations with over 91% precision; and predictive analytics forecast accident risks among migrant workers with 89% accuracy. Regional case studies highlight disparities, such as a 60% reduction in fall incidents in the United Arab Emirates through convolutional neural network (CNN) based surveillance, contrasted with barriers in Ghana, including high implementation costs and cultural resistance. Despite these advancements, challenges persist, including privacy concerns, technological limitations, and inadequate infrastructure in low-resource settings. The review underscores the need for explainable AI models, adaptable frameworks for diverse environments, and harmonized international regulations to ensure equitable and effective deployment of AI-driven safety systems.

Keywords: *Artificial Intelligence; Construction Safety; Ethical Governance; Predictive Analytics; Real-time Monitoring.*

1. INTRODUCTION

Occupational fatalities in the construction industry represent approximately 20% of global work-related deaths, primarily resulting from electrocution, falls, and equipment misuse. These incidents are often exacerbated by dynamic work environments and human error (Jaafar et al., 2018; Saleh & Othman, 2022). Traditional safety practices, including manual inspections and reactive hazard assessments, have proven inefficient, with reported accuracy rates between 50% and 60% and delays of up to three days in risk identification (Jaafar et al., 2018; Tamoor et al., 2023). The economic impact of workplace injuries, exceeding $170 billion annually, underscores the urgent need for more effective safety interventions (Vitharana et al., 2015). Recent advances in Artificial Intelligence (AI) offer promising alternatives to conventional safety protocols. AI-driven systems enable automation in compliance monitoring, structural analysis, and real-time data integration from wearables, drones, and Internet of Things (IoT) devices. For example, IoT-based structural health monitoring can identify material degradation earlier than manual methods (Plevris & Papazafeiropoulos, 2024), while AI-powered simulations can model structural resilience under environmental stress (Sargiotis, 2024).

This study aims to evaluate the potential of AI-based technologies in enhancing worker safety within construction environments. Specifically, it examines the efficacy of systems such as wearables, drones, and computer vision in reducing risks related to falls, environmental exposure, and equipment hazards. Notable findings include a 40% reduction in heatstroke incidence with wearable use (Tamoor et al., 2023) and the ability of drones to perform structural inspections in under two hours with high precision (Häikiö et al., 2020). Additionally, the study investigates regional disparities in AI adoption, (Shanti et al., 2021) as well as barriers in countries like Ghana, where adoption is hindered by financial constraints and cultural resistance (Acheampong et al., 2025; Mustapha et al., 2024). By addressing issues of scalability, ethical concerns, and regulatory fragmentation, this review contributes to a more comprehensive understanding of the transformative role AI can play in construction safety management.

2. METHODOLOGY

This study employs a structured Systematic Literature Review (SLR) guided by established frameworks such as PRISMA and Kitchenham (Kitchenham et al., 2009; Ogunmakinde et al., 2024). The process is organized into four phases: planning, selection, execution, and analysis. Each tailored to the study's objectives and summarized in Figure 1 to ensure rigor, transparency, and reproducibility.

The primary objective was to assess how AI-driven systems contribute to improving safety monitoring in construction environments. To guide the review, a structured protocol was developed that included the definition of inclusion and exclusion criteria, database selection, Boolean search strategy, and a multi-stage screening process.

Studies were included in this review if they met the following criteria: (1) publication in peer-reviewed journals between 2017 and 2025; (2) a primary focus on the real-world application of AI technologies in construction worker safety; (3) publication in the English language; and (4) provision of empirical results, either quantitative or qualitative.

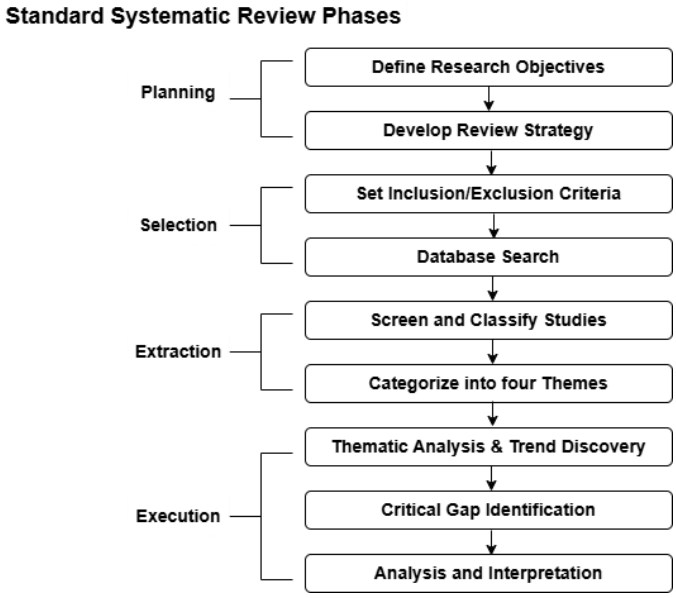

Figure 1: Method and steps of systematic literature review (SLR)

Conversely, studies were excluded if they were conceptual or theoretical without practical validation, if they addressed general industrial safety outside the construction context, if they were published in languages other than English, or if they focused on unrelated safety domains such as environmental protection. To identify relevant literature, a comprehensive search strategy was employed using Google Scholar as a supplementary tool to broaden access across disciplines. Boolean queries were applied, and although Google Scholar does not support database filtering, each article's publication venue and indexing status were manually verified via DOI metadata and publisher records. The final dataset comprised 88 peer-reviewed studies published between 2017 and 2025, sourced from the following databases: Scopus (n = 46), Google Scholer (n = 40), Research Gate (n = 36), ScienceDirect (n = 17), and other reputable academic sources (n = 25). This hybrid approach ensured both methodological rigor and broad disciplinary coverage, in alignment with systematic review standards.

The Boolean queries used included:

- ("artificial intelligence" OR "AI") AND ("worker safety monitoring" OR "worker safety") AND ("construction environment" OR "construction sites")
- ("AI-driven systems" OR "AI-powered systems") AND ("worker safety" OR "worker safety monitoring") AND ("construction industry" OR "construction environments")
- ("artificial intelligence") AND ("safety monitoring systems") AND ("construction worker safety")
- ("AI applications" OR "AI technologies") AND ("worker safety monitoring") AND ("construction sites" OR "construction environments")
- ("real-time safety monitoring" OR "real-time hazard detection") AND ("AI-driven") AND ("construction worker safety")

These initial records were subjected to a multi-stage screening process as described below.

1. Duplicate Removal.
    - 17 duplicate records were identified and removed across databases.
2. Title and Abstract Screening.
    - Of the remaining 147 articles, 12 were excluded for irrelevance to AI-driven worker safety monitoring in construction (e.g., studies focused on non-construction sectors or unrelated AI applications).
3. Full-Text Review.
    - 135 articles underwent full-text assessment against predefined inclusion and exclusion criteria.
    - Exclusions at this stage were as follows.
        - 14 studies excluded for lacking empirical data or real-world validation.
        - 11 studies excluded due to being conceptual or theoretical without actionable insights.
        - 8 studies excluded for language other than English.
        - 14 studies excluded for focusing on unrelated safety topics outside worker monitoring (e.g., environmental safety).
4. Final Inclusion.
    - A total of 88 peer-reviewed studies met all criteria, providing empirical evidence on AI applications for worker safety monitoring in construction environments.

The selected 88 studies were then classified into four thematic areas to structure the analysis and synthesis effectively.

Table 1: Thematic categories of the literature review

No.	Category	Description
1	AI Technologies in Construction Safety	Identifying AI technologies that are increasingly applied to multiple facets of construction safety, primarily focusing on fall detection and prevention, unsafe act identification, behaviour monitoring, and predictive safety modelling.
2	Performance Evaluation of AI Safety Systems	Assessing the effectiveness of AI safety systems in construction requires comprehensive evaluation metrics, including accuracy, precision, recall, other performance indicators and model comparison
3	AI's Role in Labour Displacement	Explores ethical and workforce-related implications, including resistance, retraining needs, and job shifts.
4	Research Gaps and Future Directions	Identifies unresolved challenges including implementation barriers, privacy issues, and scalability.

3. LITERATURE REVIEW

The motivation for conducting this review stems from the urgent need to enhance safety standards in the construction industry, one of the most hazardous sectors globally, responsible for approximately 20% of occupational fatalities (Jaafar et al., 2018).

Traditional safety measures, including manual inspections and reactive hazard checklists, often suffer from inefficiency, high costs, and delayed risk detection, with accuracy levels ranging from 50% to 60% and inspection times extending over several days (Jaafar et al., 2018; Wu et al., 2020). Artificial Intelligence driven systems present promising alternatives by automating hazard detection, enabling real-time monitoring, and facilitating predictive risk management (Kim et al., 2025; Shanti et al., 2021; Tamoor et al., 2023). This review was undertaken to achieve three primary objectives. First, it aims to evaluate the effectiveness of various AI technologies such as drones, wearable devices, and computer vision systems in enhancing worker safety monitoring within construction environments. Second, it seeks to examine regional disparities in the adoption of AI-based safety systems and their corresponding impact on safety outcomes across different socioeconomic contexts. Third, the review identifies critical research gaps associated with global implementation, including challenges related to scalability and ethical concerns such as data privacy and algorithmic bias (Falco et al., 2021; Jaafar et al., 2018; Mustapha et al., 2024).

3.1 AI TECHNOLOGIES IN CONSTRUCTION SAFETY

Falls are a leading cause of injuries and fatalities on construction sites, with many studies using AI models like CNNs and deep learning to detect falls in real-time by analyzing video feeds and issuing alerts (Aslam & Badi, 2025; Kim et al., 2025; Shanti et al., 2021; Tunji-Olayeni et al., 2018). Wearable AI-enabled sensors monitor posture and movement to proactively predict fall risks (Tamoor et al., 2023), while behaviour recognition algorithms trained on annotated datasets accurately classify risky actions and notify site managers instantly (Abioye et al., 2021; Mohan & Varghese, 2019; Tang, 2024; Vitharana et al., 2015). Advanced systems employ multimodal data fusion combining video, audio, and sensor inputs for comprehensive behaviour tracking (Manuel et al., 2024). Predictive analytics using historical and real-time data forecast potential accidents based on site conditions and environmental factors, often integrated with BIM for spatial hazard mapping and dynamic risk assessments (Bajwa, 2025.; Gnoni et al., 2020; Okpala et al., 2020; Tamoor et al., 2023). IoT sensors enable continuous risk data collection to support preventive interventions (Abbas & Duijster, 2025; Barrera-Animas & Davila Delgado, 2023). Despite barriers in low-resource settings, AI's transformative potential in construction safety is clear, as seen with AI-powered drones reducing inspection times from days to hours with high accuracy in flaw detection (Tamoor et al., 2023). Table 2 compares AI adoption and impact between high- and low-income regions.

Table 2: Contrasting AI applications in high-income vs. low-income regions

AI Application	High-Income Regions (e.g., UAE, EU, USA, South Korea)		Low-Income Regions (e.g., Ghana, Nigeria, Malaysia)	
	Benefits	**Challenges**	**Benefits**	**Challenges**
AI-Powered Drones	100% accuracy in hazard detection Reduced inspection time from days to hours. (Tamoor et al., 2023) Real-time risk mapping	High setup costs Worker resistance Weather dependency	Potential for remote site monitoring Reduced manual labor	Limited infrastructure for data transmission Lack of skilled operators High import costs for advanced drones (Tamoor et al., 2023)
Computer Vision (PPE Detection)	91%+ accuracy in detecting safety gear. (Shanti et al., 2021) Real-time alerts for violations	Dataset diversity issues Integration with legacy systems	Basic surveillance for compliance	Lack of labeled training data. Poor lighting conditions on sites. Limited computational resources (Shanti et al., 2021)
Wearable IoT Sensors	Real-time health monitoring. Fatigue and hazard alerts.	Privacy concerns Battery life limitations (Häikiö et al., 2020), (Awolusi et al., 2019)	Low-cost solutions for migrant workers	Cultural resistance Lack of reliable power sources Minimal awareness of IoT benefits (Häikiö et al., 2020), (Awolusi et al., 2019)
Predictive Analytics	Reduced accident rates via risk prediction Customized safety training	Data integration complexity - Ethical concerns over worker surveillance (Kim et al., 2025), (Tamoor et al., 2023)	Potential to address high-risk scenarios (e.g., falls)	Scarce historical accident data - Limited AI expertise - Poor internet connectivity (Kim et al., 2025), (Tamoor et al., 2023)
AI-BIM Integration	Proactive hazard simulation Automated safety planning	High software costs Technical complexity (Mohan &	Long-term potential for compliance	Minimal BIM adoption Lack of standardized protocols

AI Application	High-Income Regions (e.g., UAE, EU, USA, South Korea)		Low-Income Regions (e.g., Ghana, Nigeria, Malaysia)	
	Benefits	**Challenges**	**Benefits**	**Challenges**
		Varghese, 2019)		Insufficient training (Mohan & Varghese, 2019)
Generative AI (e.g., ChatGPT)	Enhanced design and risk management Automated reporting	Ethical governance gaps Workforce scepticism (Rane, 2023)	Low-code tools for safety training	Language barriers Limited access to AI platforms Regulatory inertia (Rane, 2023)
AI for Regulatory Compliance	Automated audits (Falco et al., 2021) GDPR/OSHA alignment	Algorithmic bias risks Legal ambiguity	Potential to enforce safety laws	Weak enforcement institutions Corruption (e.g., bribery in Ghana, (Boadu et al., 2021)) Lack of localized AI frameworks
Key Regional Disparities	Advanced infrastructure Regulatory frameworks Funding for R&D	Workforce resistance Over-reliance on technology	Growing tech interest Low labor costs	Poor internet/electricity Fragmented policies Limited investment in AI

3.2 PERFORMANCE EVALUATION OF SAFETY SYSTEMS

Some specific studies report accuracy rates exceeding 90% for AI-based safety detection systems used in construction site monitoring. For example, Shanti et al. (2021) detail a CNN based model for PPE detection that achieved 91.26% accuracy and nearly 99% precision. Several studies employ confusion matrices to evaluate classification outcomes by comparing true positives, false positives, and false negatives. Notable works by Gao and Sultan (2023), Tamoor et al. (2023), and Kim et al. (2025) apply this technique to assess the performance of computer vision models used for onsite safety monitoring. In addition to classical metrics, advanced indicators such as the F1-score, Area Under the Curve (AUC), and Receiver Operating Characteristic (ROC) curves are increasingly adopted, particularly in cases involving imbalanced class distributions a common scenario in safety incident datasets (Manuel et al., 2024; Mohammed et al., 2024; Rane et al., 2023). As evidenced by, Gao & Sultan (2023), they have compared Faster R-CNN and YOLO models, concluding that YOLO is better suited for real-time applications due to its faster inference speed, albeit with slightly lower accuracy. Similarly, Abioye et al. (2021) advocated for ensemble learning approaches, which improve detection robustness by aggregating predictions from multiple models. A common theme across these studies

is the trade-off between model accuracy and computational complexity. To address this, some researchers, such as Manuel et al. (2024), recommend lightweight models that can be deployed on edge devices in resource-constrained environments without significantly compromising detection performance. These metrics provide a more nuanced evaluation by balancing sensitivity and specificity, offering insights into the robustness of AI systems under varied site conditions.

3.3 AI'S ROLE IN LABOUR DISPLACEMENT

The integration of AI technologies into the construction industry is increasingly automating tasks traditionally performed by manual labourers, raising significant concerns regarding labour displacement particularly for low-skilled workers (Hajirasouli et al., 2025) . Innovations such as robotic exoskeletons, drones, and collaborative robots (cobots) are now capable of executing physically demanding or repetitive activities, including lifting heavy materials and performing routine safety inspections, thereby reducing the demand for human intervention in these roles (Licardo et al., 2024). Positions involving manual, routine labour are especially vulnerable, whereas roles requiring advanced technical competencies such as AI programming, robotics maintenance, and data analysis are experiencing growth (Alcover et al., 2021; Morandini et al., 2023). In the construction sector, upskilling initiatives will be critical in enabling workers to manage, operate, and collaborate effectively with AI-driven systems, thus supporting a more resilient and technologically adaptive workforce (Grant Nwaogbe et al., 2025).

3.4 RESEARCH GAPS AND FUTURE DIRECTIONS

According to Shanti et al. (2021), Gao and Sultan (2023), Okpala et al. (2020), and Gnoni et al. (2020), current AI safety frameworks in construction lack scalability, fail to integrate heterogeneous data sources effectively, and do not support advanced analytics or real-time decision-making. Existing systems tend to be narrowly focused, addressing discrete safety components such as PPE compliance or fall detection, without offering a comprehensive or integrative perspective. For example Bajwa, (2025) explicitly emphasizes the need for robust, end-to-end frameworks capable of managing diverse safety risks and operational variables across multiple construction phases. AI tools often function as standalone applications without interoperability with widely adopted systems such as Building Information Modelling (BIM) and project management software, resulting in fragmented safety monitoring solutions that limit efficiency and scalability, to overcome this, Okpala et al. (2020) and Manuel et al. (2024) emphasize the development of standardized interoperability protocols and middleware architectures to enable seamless data exchange and coordinated safety workflows across platforms.

Existing research on AI-driven construction safety predominantly focuses on a limited set of hazards and tends to be conducted under controlled or narrowly defined site conditions (Aslam & Badi, 2025; Kim et al., 2025; Vitharana et al., 2015). Recent studies have emphasized the importance of extending AI-based monitoring systems to diverse environmental contexts, such as underground construction, remote or inaccessible job sites, and developing regions, areas where data availability is often limited and infrastructure constraints pose significant implementation barriers (Barrera-Animas & Davila Delgado, 2023), (Abbas & Duijster, 2025).

4. DISCUSSION

This systematic review aimed to evaluate the effectiveness of AI technologies in enhancing worker safety monitoring, examine regional disparities in AI adoption, and identify key gaps in global implementation, scalability, and ethical considerations. In relation to Objective 1, the findings indicate that AI technologies significantly improve safety outcomes. For instance, AI-powered drones have reduced inspection times from 2–3 days to approximately 1.5 hours while maintaining near-perfect accuracy (Tamoor et al., 2023). Similarly, computer vision systems have achieved 91.26% precision in detecting PPE violations (Shanti et al., 2021), and predictive analytics models have forecasted migrant worker accidents with an accuracy rate of up to 89% (Kim et al., 2025).

Regarding Objective 2, the review reveals clear regional disparities in AI adoption and effectiveness. High-income countries, such as the United Arab Emirates and South Korea, have implemented AI technologies with measurable success—for example, a 60% reduction in fall-related incidents in the UAE through CNN-based surveillance (Shanti et al., 2021), and enhanced safety outcomes for migrant workers in South Korea using predictive models (Kim et al., 2025). Conversely, in low-income contexts such as Ghana, implementation is hindered by financial barriers (52%) and cultural resistance (30%) (Acheampong et al., 2025; Mustapha et al., 2024), limiting the scalability and utility of AI systems in such environments.

In addressing Objective 3, this review identifies several persistent challenges that hinder the global applicability and effectiveness of AI-driven safety monitoring systems. Chief among these are the opacity of black-box AI models, which limit explainability and hinder user trust (Gao & Sultan, 2023; Yang et al., 2024), and the risks of privacy violations stemming from surveillance-based tools such as computer vision and wearables (Aloisi & Gramano, 2019). Furthermore, algorithmic bias remains a critical concern, particularly when AI systems are trained on non-representative datasets, leading to unequal safety outcomes across worker groups (Falco et al., 2021). These technological and systemic issues are further compounded in low-resource settings by inadequate digital infrastructure and limited access to reliable connectivity (Acheampong et al., 2025; Boadu et al., 2021), restricting the scalability and adaptability of AI technologies.

Ethical considerations are central to AI's responsible deployment. Key issues include data privacy, algorithmic bias, and the lack of transparency in AI decision-making processes. These concerns are particularly acute in safety-critical sectors like construction. The literature highlights the necessity for transparent, explainable AI systems and the adoption of enforceable regulatory frameworks (Falco et al., 2021; Villegas-Ch et al., 2024). Mechanisms such as the AAA framework and international policy alignment (Cha, 2024) may help address these challenges by enhancing accountability and fostering public trust in AI systems.

A critical finding of this review is the lack of longitudinal research. Approximately 88% of the studies reviewed did not include long-term performance evaluations. This gap limits our understanding of how AI systems perform over time, particularly in relation to maintenance demands, risk adaptability, and performance degradation. For example, while AI-powered inspection drones offer short-term efficiency, there is limited evidence on their long-term effectiveness across varying construction phases and environmental conditions (Tamoor et al., 2023). Similarly, workforce adaptation and reskilling remain

underexplored, especially concerning the impact of AI on productivity and safety behaviour (Li et al., 2022; Trivedi & Alqahtani, 2024). In order to create focused AI literacy programs for site workers and safety officials, industry leaders should collaborate with vocational schools. Legislators must provide tax breaks or subsidies to building companies that spend money on worker training connected to AI.

Another significant concern is the geographic imbalance in the literature, with a strong concentration of studies originating from high-income countries. Expanding AI field studies to low and middle-income countries (LMICs) is critical, given the unique contextual challenges they face, such as informal construction practices and exposure to extreme climatic conditions (Mustapha et al., 2024; Shanti et al., 2021; Tunji-Olayeni et al., 2018). Solutions such as IoT-enabled monitoring systems must be tailored for low-resource settings to overcome infrastructural and socio-cultural barriers (Awolusi et al., 2019; Hinze et al., 2022).

To fully leverage AI's transformative potential while mitigating its risks, policy and industry efforts must focus on two fronts: (1) developing ethical AI governance structures, and (2) investing in workforce reskilling initiatives. Regulatory mechanisms should target critical issues such as algorithmic fairness, data protection, and model transparency. Furthermore, policy initiatives must support tools like explainable AI, algorithm audits, and the standardization of safety metrics across jurisdictions (Cha, 2024; Falco et al., 2021).

Emerging AI paradigms also present promising directions for future research. Federated learning, which allows decentralized model training across multiple construction sites without sharing raw data, enhances both privacy and generalizability (Berkani et al., 2025; Li et al., 2022). Integrating federated learning into hazard prediction models (e.g., fall risks) may significantly improve scalability across diverse site conditions. Edge AI, which enables on-device processing in drones and wearables, can enhance real-time decision-making, especially in regions with limited cloud connectivity (Bajwa, 2025; Rane et al., 2023; Tunji-Olayeni et al., 2018). Finally, the integration of AI-driven digital twins, combining BIM, IoT, and AI for proactive risk forecasting, remains underexplored in construction safety and warrants further investigation (Gnoni et al., 2020; Pan & Zhang, 2023).

5. CONCLUSION

This review confirms that AI technologies such as drones, computer vision, and predictive analytics significantly enhance construction safety by automating hazard detection, improving monitoring precision, and enabling proactive risk management. However, their adoption remains uneven due to infrastructure limitations, high costs, and ethical concerns, particularly in low-resource settings. Key challenges include algorithmic bias, privacy risks, and the lack of long-term evaluations. Addressing these issues through explainable, scalable, and context-sensitive AI frameworks is essential for ensuring the responsible and equitable integration of AI into global construction practices.

ASSESSING FACTORS INFLUENCING WORKER RETENTION IN THE INDIAN CONSTRUCTION INDUSTRY

Akumoni Pegu[1], Rohit Sahu[2] and Sparsh Johari[3]

ABSTRACT

India's real estate and construction sector has grown substantially over the years. Although many technological advancements have occurred to aid construction, a high demand for construction labourers remains. The construction industry faces issues concerning high labour turnover, which threatens project continuity and efficiency. This study assesses the key factors influencing worker retention in the Indian construction industry. The study adopted a mixed methods approach by identifying the factors from the existing literature, a structured survey tool was developed, and field data were collected through a questionnaire with 159 construction workers. The responses were evaluated using a 5-point Likert scale. The results reveal that wage delays, lack of safety measures, poor living conditions, limited social security, and insufficient skill development opportunities are primary deterrents to worker retention. Findings emphasize that improving financial stability, enhancing workplace safety, fostering supervisor support, and providing growth opportunities are essential for workforce stability. The study proposes actionable strategies for construction companies and policymakers to mitigate turnover and improve long-term labour retention. It offers a holistic insight into the socio-economic and organizational challenges construction workers face in India.

Keywords: *Construction worker; Socio-economic factors; Worker retention.*

1. INTRODUCTION

The construction industry is one of the leading indicators of India's economic development, contributing nearly 9% to the national GDP (Construction Skill Development Council of India, 2022). The sector continues to expand rapidly, underscoring its crucial role in infrastructure growth and job creation. Despite such significant importance, the industry faces persistent challenges in retaining its workforce. The construction industry stands vulnerable to this persisting issue, with several studies (Ayodele et al., 2022; De Winne et al., 2018) underscoring the numerous challenges the construction industry faces.

In recent years, many researchers have focused on why employees voluntarily leave their jobs, exploring the main reasons behind labour turnover (Carmeli & Weisberg, 2007; Hausknecht & Trevor, 2010). Labour turnover is important in human resource management, affecting how companies plan and manage their workforce (Arokiasamy et al., 2013). This is especially crucial in the construction industry, where many workers are involved. High labour turnover can also increase costs and reduce organizational productivity (De Winne et al., 2018).

Studies by Ayodele et al. (2022) and De Winne et al. (2018) have identified core deterrents to retention, including wage delays, unsafe working conditions, inadequate living arrangements, and social security. Workers not within the purview of their primary employers have often faced difficulties accessing protections and benefits. Furthermore, a significant gap exists between the intent of labour welfare policies, such as the Building and Other Construction Workers' (BOCW) Act, and their actual implementation on the ground level.

Effective workforce planning is essential for improving organisational efficiency. Inconsistent planning can lead to employee turnover, which disrupts overall workforce performance and reduces competitiveness (Duda & Zurkova, 2013). Employees often leave voluntarily due to low job satisfaction, lack of job security, alternative job opportunities, and poor work–life balance (Ayodele et al., 2022). These factors are linked to poor performance and low productivity in the construction sector.

The sector heavily depends on migrant and informal workers, who lack job security, social protection, and career growth opportunities (Bora, 2014). This leads to frequent job switching, particularly between project phases, creating difficulties in workforce planning and increasing recruitment and training costs (ILO, 2020). Regional disparities, inconsistent labour policies, and the lack of long-term employment contracts further complicate the situation.

Although existing studies have examined turnover drivers such as pay dissatisfaction, insufficient safety, or weak supervisory support, limited research integrates these diverse factors holistically, especially from the perspective of the most affected workers. Most past studies focus on organizational policies or macroeconomic analysis, creating a significant gap in understanding the nuanced, ground-level realities of labour retention in the Indian construction sector.

This study explores the key factors influencing worker retention in India's construction industry, focusing on workers' perspectives. It adopts a comprehensive, multi-dimensional framework that integrates financial, health-related, work-related, and state-related factors to reflect construction labourers' complex realities, particularly those from informal and migrant backgrounds. The study provides a grounded understanding of retention's most critical issues by analysing these dimensions through structured field data. The findings are intended to support construction firms and policymakers in designing more targeted and effective retention strategies that enhance workforce stability, reduce project disruptions, and promote long-term sectoral growth.

2. LITERATURE REVIEW

Financial stability has consistently emerged as a fundamental driver of worker retention in the construction industry. Studies such as Palaniappan et al. (2023) highlight that pay satisfaction is closely linked to worker well-being and long-term commitment to

employers. Consistent and adequate earnings are often cited as primary motivators, with the widespread preference for overtime opportunities reinforcing the value workers place on supplemental income. Furthermore, research by Ayodele et al. (2022) and Duda and Zurkova (2013) suggests that the loss of skilled and experienced workers due to poor financial incentives can lead to significant productivity losses and increased costs for construction firms.

Worker retention remains a persistent challenge in the global construction industry, driven by complex, interrelated factors such as job satisfaction, wage stability, working conditions, and career growth opportunities. Arokiasamy et al. (2013) highlighted that voluntary turnover in the private sector often stems from dissatisfaction with pay, lack of career advancement, and poor organizational culture, equally relevant issues in the construction industry. Similarly, Lambert and Hogan (2008) established that job satisfaction and organizational commitment significantly shape turnover intentions, while Carmeli and Weisberg (2007) emphasized the role of emotional and psychological attachment in predicting retention.

In the construction context, Ayodele et al. (2022) developed a framework identifying project-specific dynamics, work-life imbalance, and lack of supervisor support as key contributors to labour turnover. These findings are reinforced by Kissi et al. (2024), who found that supervisor support significantly reduces turnover intentions when mediated by worker engagement.

Duda and Zurkova (2013) demonstrated that high turnover disrupts productivity, inflates operational costs, and leads to the loss of institutional knowledge. Ohueri et al. (2018) further noted that motivation strategies, including fair compensation and skill recognition, are essential to improve retention and productivity. These insights are echoed in India's context, where the Construction Skill Development Council of India (2022) emphasized the urgent need to align skilling programs with retention objectives, especially given the sector's heavy reliance on informal, often migrant, labour.

Transformational leadership has also been recognized as critical in improving organizational retention. Bass and Avolio (1994) argued that leaders who inspire, mentor, and provide individualized support can reduce turnover by fostering loyalty and motivation. Furthermore, macro-level studies such as ILO (2020) and OECD (2019) advocate for policy interventions to support fair wages, safe working conditions, and long-term employment contracts to mitigate workforce instability. Samanta and Gochhayat (2023) also identified poor safety practices as a significant deterrent to retention in India's construction sector.

To fill this gap, the study aims to identify and consolidate the key factors affecting the retention of construction workers through a comprehensive literature review, analysing the data through a survey to know actual worker perceptions. This approach highlights the most influential retention drivers and explores potential reasons for any observed discrepancies. The ultimate objective is to provide actionable recommendations for construction firms and policymakers to improve retention rates by developing targeted interventions.

3. RESEARCH METHOD

This study employed a structured questionnaire survey as the primary method for data collection. This approach was selected due to its ability to systematically measure

multiple dimensions influencing worker retention and efficiently capture responses from a relatively large number of participants. The questionnaire was developed based on key themes identified in the literature review and was simplified to suit the literacy levels of many construction workers, ensuring inclusiveness and clarity. Similar methodologies have been adopted in workforce studies by Ayodele et al. (2022) and Ohueri et al. (2018), demonstrating the validity of structured surveys for field-based research in developing countries. As illustrated in Figure 1, the research process consisted of three key phases: identifying influencing factors through literature synthesis, developing and administering the questionnaire, and statistical analysis of collected data.

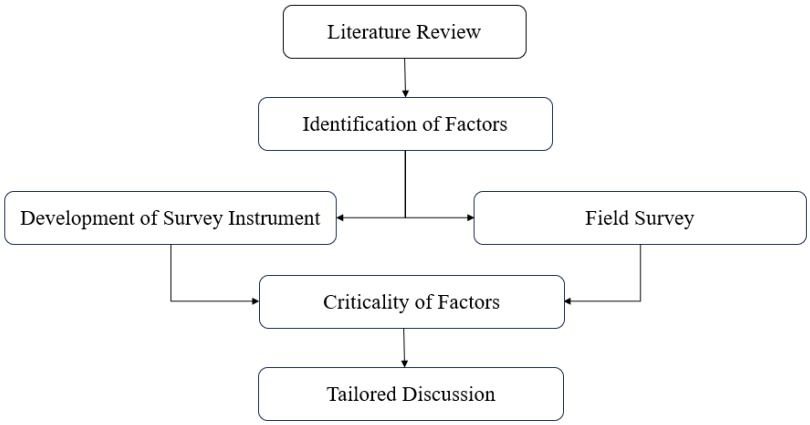

Figure 1: Research methodology

3.1 IDENTIFICATION OF WORKER RETENTION FACTORS

This initial stage consisted of a comprehensive review of scientific literature, industry reports, and policy documents to recognize the key determinants of construction worker retention in India. This process synthesized thirteen retention-related factors, representing the most frequently cited drivers influencing workers' decisions to remain in or leave their jobs. As shown in Table 1, these factors were classified into four thematic dimensions: financial, workplace, state-related, and health-related. This categorization ensures a holistic understanding of the multi-dimensional aspects that affect worker retention in the Indian construction industry.

Table 1: Factors influencing worker retention

Category	Code	Factors	Source
Finance-Related Factors	F1	Wage Satisfaction	Ayodele et al. (2022); Palaniappan et al. (2023)
	F2	Timeliness of Pay	ILO (2020)
	F3	Overtime Opportunities	Ayodele et al. (2022)
	F4	Incentives/Rewards	Duda and Zurkova (2013)
Health-Related Factors	F5	Healthcare Access	ILO (2020); WHO (2016)
Work-Related Factors	F6	Work Relocation Frequency	Zhao et al. (2005)
	F7	Supervisor Behaviour	Kissi et al. (2024); Bass and Avolio (1994)

Category	Code	Factors	Source
	F8	Personal Protective Equipment Kit	Samanta and Gochhayat (2023); ILO (2020)
State-Related Factors	F9	Accommodation Quality	Bora (2014); ILO (2020)
	F10	Welfare Measures	OECD (2019); ILO (2020)
	F11	Skill Development Opportunities	CSDCI (2022); OECD (2019)
	F12	Social Security Benefits	ILO (2020)
	F13	Grievance Redressal Mechanisms	Arokiasamy (2013); ILO (2020)

3.2 DATA COLLECTION

The data for this study were gathered through a structured questionnaire administered to workers engaged in a construction project in Guwahati, India. A total of 159 responses were collected through in-person interactions on a 5-point Likert scale, as shown in Table 2. Due to the low literacy levels among respondents and the absence of prior exposure to formal surveys, each question was explained individually in the simplest and most relatable way.

The ethical principles of voluntary participation, anonymity, and informed consent were maintained throughout the data collection process.

Table 2: Likert scale adapted for criticality rating

Scale	Description
1	Very low criticality
2	Low criticality
3	Moderate criticality
4	High criticality
5	Very high criticality

3.3 DATA ANALYSIS

The collected data were analysed using descriptive statistical methods suitable for exploratory research involving ordinal Likert-scale responses. This approach effectively summarizes participant perceptions and identifies key factors influencing worker retention. Using SPSS, the mean, standard deviation, skewness, and kurtosis for each of the thirteen factors have been calculated. These metrics helped rank the factors based on their perceived criticality among workers.

Descriptive analysis was chosen due to the study's exploratory nature and moderate sample size (n = 159). Similar approaches have been adopted in related construction workforce studies, such as those of Ayodele et al. (2022) and Ohueri et al. (2018), validating their relevance and applicability in similar contexts.

4. RESULTS AND DISCUSSION

This section presents the findings from the field survey and the subsequent statistical analysis of factors influencing worker retention. The data collected through the structured questionnaire were analysed using descriptive statistical techniques widely used in exploratory studies to interpret perception-based data.

This method was selected because it effectively summarizes and ranks multiple variables based on participant responses, particularly when dealing with a moderate sample size and ordinal-scale data such as Likert ratings. Similar approaches have been adopted in construction workforce studies, including Ayodele et al. (2022) and Ohueri et al. (2018), where descriptive statistics were used to evaluate labour-related factors in developing countries.

In this study, each of the thirteen retention factors has been rated on a 5-point Likert scale, and their mean scores, standard deviations, and distribution characteristics (including skewness and kurtosis) were calculated using SPSS software. These statistical measures helped identify which factors were most critical to the respondents and how consistent their responses were across the sample.

Descriptive analysis was considered appropriate given the study's objective of gaining foundational insight into worker retention from a field-based perspective. More advanced statistical techniques were not applied, as the study was exploratory and the available sample size (n = 159) did not support robust inferential modelling. Nevertheless, the chosen approach effectively captured meaningful patterns in worker perceptions and laid the groundwork for future, more detailed analyses.

4.1 DEMOGRAPHIC PROFILE OF THE RESPONDENTS

The surveyed population consisted of all male construction workers, 159 workers in total, reflecting the gender imbalance traditionally seen in India's construction industry. No female workers were present at the selected construction site during data collection. The workforce was primarily concentrated in the 21–40 years bracket, with the highest proportion falling within the 21–30 age group, as shown in Figure 2. This suggests that construction work continues to draw from the labour force's younger, physically active segment. The presence of workers above 40 years, though lower in number, indicates a continued dependence on long-serving labourers who may not have transitioned to more stable or skilled occupations.

Professionally, the survey captured respondents engaged in key trades such as masonry, carpentry, bar bending, tiling, and scaffolding, as shown in Figure 3. Among these, the most common occupation was listed as 'Other', which often includes general helpers and support labourers not tied to a specific skill. This highlights the high prevalence of multi-purpose unskilled workers, whose retention is critical to daily site operations.

Age distribution analysis indicates a relatively young to middle-aged workforce with 34% of respondents falling in the 25-34 age bracket, followed by 29% in the 35-44 category. The 18-24 age group constituted 20%, while workers above 45 represented 17% of the sample. This age distribution aligns with industry patterns where physical labour intensity favours younger and middle-aged workers.

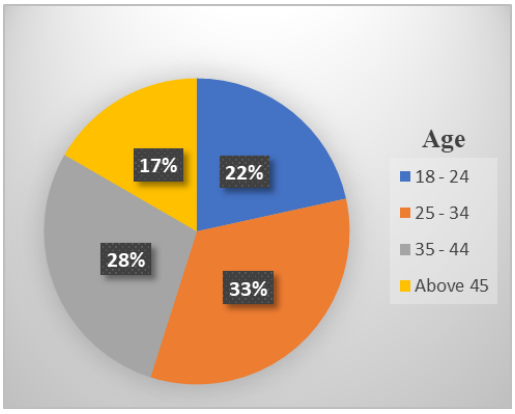

Figure 2: Age distribution of respondents

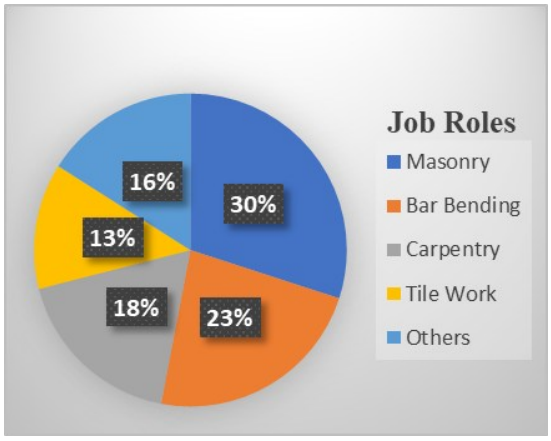

Figure 3: Job role distribution

Regarding job specialization, the respondents represented diverse construction trades, such as 30% of the respondents belong to masonry, 23% bar bending, 18% carpentry, 13% tile work, and 16% other specialized roles, as shown in Figure 3. Work experience distribution indicated that 8% had less than 1 year, 37% had 1-5 years, 42% had 5-10 years of experience, and 13% had over 10 years of construction experience, as shown in Figure 4.

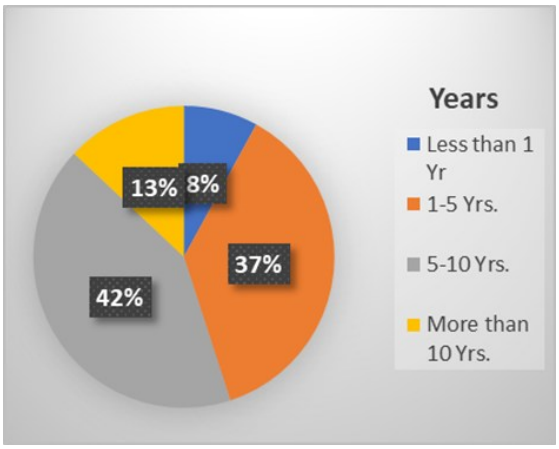

Figure 4: Work experience distribution

4.2 RELIABILITY ANALYSIS

The study, 159 workers were surveyed out of 300 contacted workers, meaning about 53% came forward for the exercise. The reliability analysis was conducted using Cronbach's alpha to assess the internal consistency of the survey instrument. Cronbach's alpha is a prerequisite for ensuring that subsequent analyses, such as criticality assessment, are based on dependable and valid data. The analysis yielded a Cronbach's alpha coefficient of 0.730, exceeding the commonly accepted threshold of 0.7, which indicates satisfactory reliability (Chammout et al., 2024).

4.3 CRITICALITY OF FACTORS

The statistical analysis provides critical insights into the various retention factors. Wage satisfaction and accommodation quality emerged as the most critical factors for worker retention. Workers rated wage satisfaction at an average of 4.38, with responses tightly clustered around this high value, as indicated by the slight variation in responses. Similarly, accommodation quality received an average rating of 4.35, with somewhat more varied responses across participants. The strong negative skewing of responses for both factors confirms that worker opinions were heavily concentrated at the higher end of the scale.

Further analysis revealed that nearly 72% of respondents considered wage satisfaction the most significant, while 70% considered accommodation quality significant. Notably, no workers rated wage satisfaction below a three on the scale, and accommodation quality was rarely rated below a 2, underscoring the universal significance of these factors across the entire construction workforce.

Overtime opportunities also demonstrated relatively high importance, with an average rating of 3.94 and more than half (55%) of workers considering it significant. Though responses tended toward the higher end of the scale, they showed greater variability than the wage and accommodation factors, suggesting somewhat less consensus among workers regarding the importance of overtime availability.

Most factors fell into the moderate importance range (between 2.97 and 3.26), including safety kit provision, healthcare access, skill development, social security, supervisor behaviour, grievance redressal, welfare measures, and work relocation concerns. These factors exhibited relatively normal distributions with skewness values close to zero, ranging from -0.34 to 0.27, and standard deviations between 0.73 and 0.91.

Cross-tabulation analysis revealed interesting patterns within these moderately rated factors. Workers with more than five years of experience assigned slightly higher importance to skill development opportunities, rating it at an average of 3.21, compared to less experienced workers who gave it a lower average rating of 2.87. This difference suggests that career progression becomes more salient as workers gain experience and tenure in the construction industry. Similarly, workers above 35 placed greater emphasis on social security benefits, with an average rating of 3.18, while younger workers rated this factor lower at approximately 2.86. This age-based variation likely reflects life-stage concerns, with older workers increasingly focusing on long-term financial security and benefits as they progress through their careers and take on greater family responsibilities.

Timeliness of pay received the lowest average rating among all factors at 2.81, though this still falls within the moderate importance range. Workers' opinions about this factor

showed considerable variability, as evidenced by the wider spread of responses compared to other factors. This suggests diverse perspectives on the importance of payment timing within the workforce. The mean importance ratings of these factors were ranked on the 5-point Likert scale and are shown in Table 3.

Table 3: Criticality of factors influencing worker retention

Factor	Mean	Standard Deviation	Rank by Mean	Distribution Characteristics	
				Skewness	Kurtosis
Wage Satisfaction	4.38	0.50	1	-1.50	0.38
Accommodation Quality	4.35	1.06	2	-1.35	0.32
Overtime Opportunities	3.94	1.11	3	-0.82	-0.06
Incentives/Rewards	3.26	0.91	4	0.27	-0.02
Healthcare Access	3.05	0.77	5	-0.34	0.79
Safety Kit Provision	3.02	0.73	6	-0.23	0.09
Supervisor Behaviour	3.02	0.74	7	0.06	0.12
Skill Development Opportunities	3.02	0.78	8	0.05	-0.25
Social Security Benefits	3.00	0.79	9	0.00	0.26
Grievance Redressal Mechanism	3.00	0.74	10	-0.10	0.18
Welfare Measures	2.99	0.75	11	-0.08	0.03
Work Relocation Frequency	2.97	0.74	12	0.05	-0.12
Timeliness of Pay	2.81	1.14	13	-0.71	-0.71

5. DISCUSSION

This section examines the key factors considered in the study, how important they were rated, and what they mean for worker retention. It also helps identify which issues need the most attention to improve workforce stability.

5.1 FINANCE-RELATED FACTORS

The finance-related factors adopted in the study are connected to the economic benefits of workers, such as wage satisfaction, timeliness of pay, overtime opportunities, and incentives/rewards. Among all the factors considered in the study, wage satisfaction is the most critical, as indicated by the survey results, underscoring its importance for labour retention. The variation in ratings among the respondents was also drastically less than the other factors, implying that most individuals deem it important. The findings correlate perfectly with financial remuneration directly linked to worker motivation, job satisfaction, and organizational loyalty (Ayodele et al., 2022; Palaniappan et al., 2023).

On the other hand, overtime opportunities are slightly less rated, but individuals differ in their responses. Incentives and rewards are found to be less critical, with variations in responses being on the higher side since their renumeration is subject to various factors within or beyond one's control. Past studies (Duda & Zurkova, 2013) indicate that non-

wage financial rewards can significantly influence employee morale and productivity. However, there might be certain other factors beyond this study's scope.

Interestingly, Timeliness of Pay ranked lowest among all factors, suggesting that while essential, it may be less of a distinguishing factor in environments where workers are habituated to payments getting delayed under subcontracting or working under an arrangement where regular pay is institutionalized. Nonetheless, delayed payments negatively affect worker trust and emotional well-being (ILO, 2020), indicating that this factor's influence may vary by industry or geographic context.

5.2 HEALTH-RELATED FACTORS

Although considered important in various domains, especially construction, where occupational hazards are a primary concern, health-related factors have been rated less critical for sustaining worker retention. In this study, healthcare access reflects a moderate level of importance as perceived by workers. Though not among the top, it has scored above the neutral midpoint, indicating its acknowledged relevance.

Occupational health literature consistently emphasizes the importance of accessible healthcare in mitigating work-related illnesses and ensuring long-term workforce sustainability (ILO, 2020). In this study, healthcare access was rated lower than financial factors, suggesting it may not be a top reason workers stay. However, many construction projects are in remote areas and may offer higher pay, which can influence worker decisions.

5.3 WORK-RELATED FACTORS

In this category, Supervisor behaviour, Work relocation frequency, and PPE kit provision reflect moderate concerns among workers, suggesting that the immediate work environment holds particular value in satisfaction and continuity.

Supervisor behaviour and supportive leadership have been closely associated with fostering trust, enhancing communication, mitigating job stress, and promoting a healthy work environment (Bass & Avolio, 1994). The mean score suggests that while supervisor conduct is valued, it may not be a deciding factor for many, though its latent impact on morale and conflict resolution is substantial.

In this context, Work Relocation Frequency scored lower, implying moderate discontent. However, high mobility often disrupts personal life, impairs community ties, and contributes to job dissatisfaction, especially among older or family-bound workers (Zhao et al., 2007). Organizations that frequently relocate workers without appropriate compensation or support often see higher attrition.

Including safety kit provision under work-related categories also reflects its dual role, as a safety resource and an operational expectation. Its moderate score highlights its continued relevance across domains, though the willingness to comply with safety regulations also rests considerably with the workers. Work-related factors are denoted as moderate to high criticality in this study. Improving supervisory practices and stabilizing work assignments can significantly enhance retention outcomes, particularly when aligned with professional development and well-being strategies.

5.4 STATE-RELATED FACTORS

While external to the employer, state-related factors significantly influence workers' long-term attachment to the labour force. None featured among the top critical factors, but they stand out as relevant given their scores near or just above the midpoint.

Grievance redressal and social security benefits received identical moderate critical scores, indicating a shared perception among workers about their trust in institutional arrangements. Workers are likelier to remain with employers or sectors where their concerns are heard and resolved fairly, strengthening their trust in the state and the judiciary (Arokiasamy et al., 2013). Social Security Benefits, such as pensions, insurance, and retirement plans, form a safety net that enhances workers' social well-being and long-term planning. The ILO (2020) underscores the role of social protection in reducing turnover and sustaining workforce resilience, especially in sectors vulnerable to economic volatility or occupational hazards.

Skill development opportunities scored slightly higher criticality, revealing workers' interest in career progression and a better life. Access to training not only improves retention but also boosts productivity and adaptability (OECD, 2019). Welfare measures, encompassing services like housing, canteens, and childcare, were ranked lowest among state-related factors. This may reflect either a lack of availability or low expectations from the state/employer regarding these provisions.

6. CONCLUSION

This study sought to examine and categorize the determinants of worker retention through a multi-dimensional lens encompassing finance, health, work, and state-related factors. The findings underscore that financial variables, particularly wage satisfaction and opportunities for overtime, are the most critical in retaining workers. Health and safety considerations, including access to healthcare and the provision of personal protective equipment, were moderately rated, highlighting their conditional importance, especially in sectors characterized by physical risk.

Work-related aspects, particularly supervisor behaviour and job relocation frequency, emerged as critical in shaping employees' day-to-day experience. These elements influence job satisfaction and emotional engagement, often as tipping points in retention decisions. Though often external to the organization, state-related factors support institutional trust and future security through grievance redressal, social security, and skill development programs.

Given the moderate to high criticality of many identified variables, this study recommends a prioritized, integrated approach to workforce management that combines fair compensation, safe working conditions, supportive supervision, and robust state support mechanisms. Future research may expand upon this model by investigating sector-specific retention drivers or exploring longitudinal impacts of policy interventions on workforce stability. While this study provides a broad overview of multiple retention factors, future research should focus more deeply on individual categories, such as financial incentives or organizational practices, to uncover more targeted strategies for improving worker retention.

7. LIMITATIONS

While the study provides valuable insights, several limitations should be acknowledged. The data were collected from only Northeastern India, which may not fully capture the diversity of labour dynamics across the country. As the study was done at one point, it cannot show how retention priorities change over time. The moderate sample size and focus on only workers' perspectives may also limit the findings' generalizability to other construction workforce segments.

ASSESSING KEY RISK FACTORS FOR WORKERS DURING NIGHTTIME IN THE INDIAN CONSTRUCTION INDUSTRY

Naman Srivastava[1], Rohit Sahu[2] and Sparsh Johari[3]

ABSTRACT

Construction activities are crucial for global infrastructure development, but are often accompanied by significant risks, particularly at night. The transition from day to night amplifies hazards due to inadequate lighting, disrupted routine work, fatigue, and heightened stress levels. This study uses a field-based approach, incorporating expert interviews, to identify and prioritize 17 critical safety attributes construction workers face during nighttime. The study conducted 15 expert interviews, and the Analytic Hierarchy Process (AHP) was employed to quantify and prioritize these risks in the Indian context. The attributes identified were categorised into five factors, i.e., environmental, human, work-related, equipment, and organizational. By prioritizing through AHP, work-related risks, such as construction height, emergency preparedness, and falling objects, emerge as the most critical. While equipment hazards like poor lighting and faulty electrical grounding also rank high. However, organizational issues, including lack of training and weak supervision, significantly affect safety but are often normalized in the informal sector. Notably, human factors like fatigue, sleep deprivation, and stress rank lowest, despite their known long-term impact on alertness and safety, revealing a significant gap in current safety approaches. The study highlights the need to increase awareness of often-overlooked risks, particularly human and organizational factors. The findings support policymakers and practitioners in prioritizing safety concerns, planning, supervision, and training efforts for nighttime construction. This study contributes to developing more targeted, evidence-informed safety strategies in nighttime construction in the Indian construction sector.

Keywords: *Construction Worker; Nighttime Construction; Occupational Safety.*

1. INTRODUCTION

Occupational accidents are the cause of more than 3,00,000 mortalities and 300 million injuries around the world each year (International Labour Organization, 2014). The construction industry is one of the most hazardous occupational sectors globally. In particular, these risks are magnified during nighttime operations due to reduced visibility,

disrupted circadian rhythms, and increased fatigue, making night work particularly dangerous for construction workers (Amiri et al., 2015).

One of the earliest studies to examine the differences between daytime and nighttime highway construction was conducted in Colorado in 1986 (Price, 1986), marking a foundational effort to understand the unique challenges associated with night work in the construction sector. Research on shift work's health and safety effects indicates that shift workers experience adverse health symptoms more frequently and severely than day workers (Folkard & Lombardi, 2006). There is a large body of evidence indicating that night workers, in particular, suffer from chronically impaired health and well-being, including sleep problems, headaches, anxiety, poor concentration, nervousness, mild depression, mood disturbances, cardiovascular and musculoskeletal problems (Loudoun & Allan, 2008).

During nighttime construction, the hazard level to construction workers is manifold when working with heavy machinery, operating at elevated heights (Arditi et al., 2005). These risks endanger the lives and health of construction workers, affect economic costs, and cause delays. The transition from day to night creates a complex and challenging work environment, which is very difficult for the workers. The tasks that are straightforward during the day may be hazardous at night.

Despite advancements in safety practices in the construction industry, nighttime construction remains under-researched, especially in low and middle-income countries where most infrastructure development is labour-intensive and informal. India has one of the largest construction industries in the world, employing over 70 million workers (Chellappa et al., 2021; Statista, 2024). However, research on the safety health of Indian construction workers is limited, despite the high prevalence of safety problems among construction workers. In India, the construction sector accounts for one of the highest occupational fatality rates, with estimates ranging between 11,614 and 22,080 fatalities annually between 2008 and 2012 (Patel & Jha, 2016).

In India's rapid urbanization and growing infrastructure demands, nighttime construction has become increasingly common, particularly in metropolitan cities. The Indian construction industry, predominantly informal and labour-intensive, often lacks standardized protocols for nighttime operations (Chellappa et al., 2021). As a result, to complete the tasks, the construction workers have to work more, so the construction safety is lower. The hazards become even more dangerous during nighttime construction, where reduced visibility, extreme weather, and disrupted sleep cycle contribute to an increased threat to occupational health and safety (Arditi et al., 2005).

Challenges such as inadequate lighting, absence of proper signage, insufficient protective gear, and limited health and safety monitoring contribute to increased workers' vulnerability during night shifts (Hinze & Carlisle, 1990). Despite the increasing reliance on nighttime construction, there is a notable absence of empirical research that systematically assesses the risk factors unique to these settings in the Indian context. Addressing this gap is essential for informing evidence-based safety policies and improving working conditions in India's construction sector.

Although several studies have explored construction site safety and occupational risks, most focus on daytime conditions or aggregate safety data without distinguishing between shift timings. Research addressing the specific challenges of nighttime construction, such as reduced visibility, worker fatigue, psychological stress, and lack of supervision,

remains limited, especially in low and middle-income countries like India. Furthermore, existing literature seldom applies multi-criteria decision-making methods like the Analytic Hierarchy Process (AHP) to prioritize these risks based on expert judgment. This lack of focused, empirical research on night-specific risks in the Indian construction context represents a critical gap that this study aims to address.

2. LITERATURE REVIEW

Nighttime work presents unique challenges and risks due to visibility issues, worker fatigue, and environmental factors. This review synthesizes findings from multiple studies to highlight the factors affecting nighttime operations. Nighttime work increases hazards for workers due to poor visibility and human factors such as sleep deprivation.

2.1 FATIGUE AND SLEEP DEPRIVATION IN NIGHTTIME OPERATIONS

Fatigue is a leading risk factor in nighttime construction, often resulting from disrupted circadian rhythms and insufficient rest. Sleep deprivation has been shown to impair attention and cognitive function, increasing the likelihood of accidents (Powell & Copping, 2010). In a study conducted in Vancouver, construction workers monitored with actigraphs exhibited sleep patterns far below the recommended 8 hours, correlating with a 9% increase in accident risk.

2.2 IMPACT OF SHIFT WORK AND SUBSTANCE USE

Night shifts are also a source of stress, a situation that can induce "escapist" consumption of addictive substances such as tobacco, coffee, alcohol, etc. To this must be added the problem of having to work during periods of rest that are usual for the rest of the population, such as holidays, weekends, and nights (Elrahman & Perry, 1994). All these circumstances, acting together, reduce the efficiency of the workers at the time of concentration. Night shifts are stressful, and to counteract it, workers use tobacco or alcohol to feel better and stay attentive during nighttime construction. This may be effective during the time of work, but when it becomes an addiction, then the absence of it may lead to ineffectiveness, and workers become inattentive. Working at a time when most people take rest, like nights, weekends, or holidays, makes it more challenging. This disrupts personal and social connections, which are needed to help in recovering from addiction.

2.3 LIGHTING, VISIBILITY, AND ENVIRONMENTAL HAZARDS

Similarly, lighting is an essential element of any nighttime project since it affects quality, productivity, and safety. Adequate lighting makes constructing at night as easy as constructing during the day, as it positively affects visibility. In a study by Hinze and Carlisle (1990), state highway agencies and contractors stated that adequate lighting is an important safety aspect in nighttime construction projects. Based on the study's suggestions, Hyari and El-Rayes (2006) developed illumination guidelines for nighttime highway construction and maintenance.

In addition to lighting, weather has contributed significantly to construction safety factors, especially during night shifts. Many studies show that adverse weather can influence the frequency of accidents and the seriousness of their consequences. The data also reveal that wet conditions, particularly night shifts, pose significant safety risks (Kim & Xiong, 2025). This pattern underlines the riskiness of construction work on and off-

site, especially considering that weather conditions are exacerbated by "lighting conditions"- day versus night. Low light and visibility increase the chances of falls at night, especially at height. In addition to physical injuries, falls from heights can also cause mental trauma (Zaini et al., 2020; Hyari & El-Rayes, 2006).

In addition, slippery surfaces, reduced visibility, and structural instability due to severe weather contribute to heightened accident risks. During nighttime, the temperature drops, and due to this, the moisture in the air condenses. This condensation makes the surfaces, such as walls and ground, slippery. Due to this, accidents occur, and workers slip on these surfaces and fall. If they carry a heavy object, they cause harm to themselves (Amiri et al., 2015).

2.4 EQUIPMENT, MACHINERY AND HUMAN FACTORS

Scaffolding failures, lack of personal fall protection systems, and inadequate safety barriers are primary factors leading to fall-related accidents. Unsafe working conditions at elevated platforms, combined with insufficient training on height safety protocols, significantly increase the risk of severe injuries or fatalities (Amiri et al., 2015).

Many construction accidents occur due to a lack of proper training, with workers often failing to recognize or respond appropriately to hazards in their work environment. New and inexperienced workers are at a higher risk of injury, making structured safety education and on-site training essential components of accident prevention strategies (Amiri et al., 2015; Brolin et al., 2021).

Many accidents occur due to inadequate hazard identification and risk assessment before the commencement of construction activities. Effective risk assessment strategies, such as predictive analytics and data-driven decision-making, can significantly reduce workplace hazards. Though safety awareness in the construction industry is increasing, a significant research gap remains, as most trainings focus on general or daytime risks, with minimal attention to nighttime hazards (Yang et al., 2024). There is a lack of structured studies using statistical methods to prioritize these risks for decision-making. The current study addresses this gap by identifying and evaluating the factors that impact workers' safety in nighttime construction through applying the Analytic Hierarchy Process (AHP), particularly from an Indian perspective.

3. RESEARCH METHOD

The research adopts a structured approach consisting of the following steps: identification of the factors, data collection, data analysis, computations, and results. Each step is defined in the following subsections as shown in Figure 1.

3.1 IDENTIFICATION OF RISK FACTORS

A thorough analysis was conducted from literature reviews of research articles, news articles, and government reports. This study identifies key risk factors that affect construction worker safety, specifically during nighttime operations. These factors and attributes are shown in Table 1.

3.2 AHP – BASED RISK PRIORITIZATION

The safety climate refers to the overall attitude of workers towards safety precautions and practices during construction. Thus, the information should be handled qualitatively.

Therefore, in this study, an AHP questionnaire was administered to a group of safety experts who have performed safety management tasks for an extended period to maintain the consistency of the results. To do so, a questionnaire was first formed based on the AHP technique. In AHP analysis, the evaluation criteria and alternatives are organized in a hierarchical structure, and then, the priority is determined by deriving relative importance. A flowchart of the AHP process is shown in Figure 2.

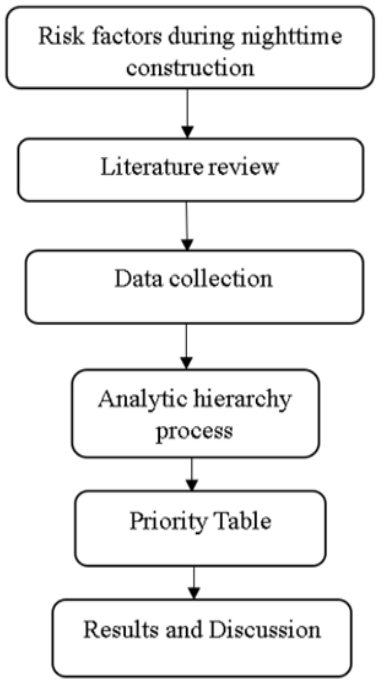

Figure 1: Research methodology flowchart

Table 1: Categorization of risk factors and attributes identified from literature

Factors	Attributes
Environmental	A1. Glare from Roadways
	A2. Extreme temperature
	A3. Slippery surface due to moisture during the night
Human	B1. Hypertension
	B2. Fatigue
	B3. Sleep Deprivation
	B4. Addictive intake
	B5. Psychological Impact
Work-related	C1. Height of construction sites
	C2. Lack of emergency readiness
	C3. Falling and Falling Objects
Equipment and Machinery Hazards	D1. Reflective PPE Kits (if not used properly)
	D2. Inadequate lighting at the construction site.
	D3. Heavy machinery operation (crane, hoists) is riskier in low visibility
	D4. Grounded electrical wiring
Organizational and Supervision	E1. Inadequate training for nighttime hazards
	E2. Improper supervision during construction

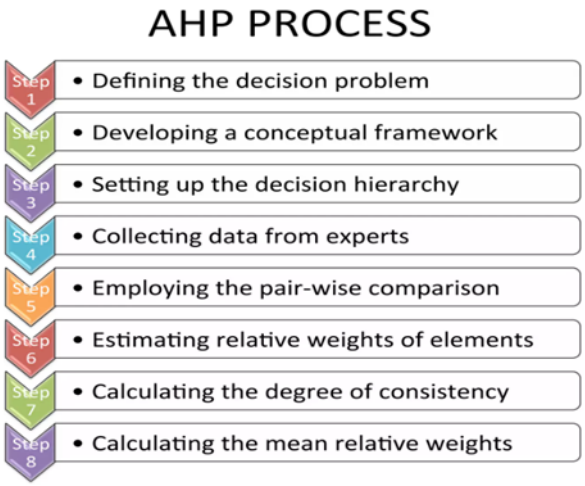

Figure 2: Flowchart of AHP process

After developing a questionnaire, industrial experts were interviewed to acquire the data to conduct AHP. The experts have given weight to the combination of two risks. This structured approach ensures that the identified risks are prioritized systematically and aligned with expert judgment.

3.3 STUDY EXPERTS

This study surveyed safety experts working at construction sites in India. The survey period was for 2 months from March to April in 2025. Out of the 20 questionnaires collected, only 15 with a consistency of 0.1 or less were selected.

As shown in Table 2, most of the surveyed experts (53.33%) had between 5 and 10 years of experience in construction safety, indicating a well-informed sample with mid-level professional insights. Among all the interviewees, all 15 were male and had graduate degrees in allied construction engineering.

Although the sample size of 15 experts is relatively limited, it aligns with established practices in AHP studies, where smaller expert panels (typically between 10–20 participants) are considered sufficient when participants have high domain expertise and consistency ratios are within acceptable thresholds (Saaty, 2008; Tsyganok et al., 2012; Nguyen et al., 2022). In this study, all selected responses had a consistency ratio ≤ 0.1, indicating reliable judgment. Moreover, the selected experts had a minimum of graduate-level education and significant field experience in construction safety, further supporting the adequacy and credibility of the sample.

Table 2: Demographic profile of safety experts participating in AHP survey

Experience (in years)	Number of experts	Percentage
less than 5 years	4	26.6
5-10 years	8	53.3
10-15 years	2	13.3
15+ years	1	6.6

3.4 ANALYSIS

In AHP analysis, the evaluation criteria and alternatives are organized in a hierarchical structure, and the priority is determined by deriving relative importance (Lim et al., 2021). For conducting AHP, the evaluation factors and attributes should be stratified to analyse the relative importance of the risk severity evaluation. The decision-making issues of this study were developed with the help of the experts in the form of a stratified pattern as shown in Figure 3. Therefore, the goal of AHP analysis in this study is to derive the importance of the safety climate evaluation factors. This comprises five dimensions (factors) and 17 items (attributes). Refer to Table 1 for details on the evaluation items for each level in Figure 3. The items of each dimension are analyzed after determining the relative importance of the dimensions of the first level. Subsequently, the relative priorities of the evaluation factors are derived.

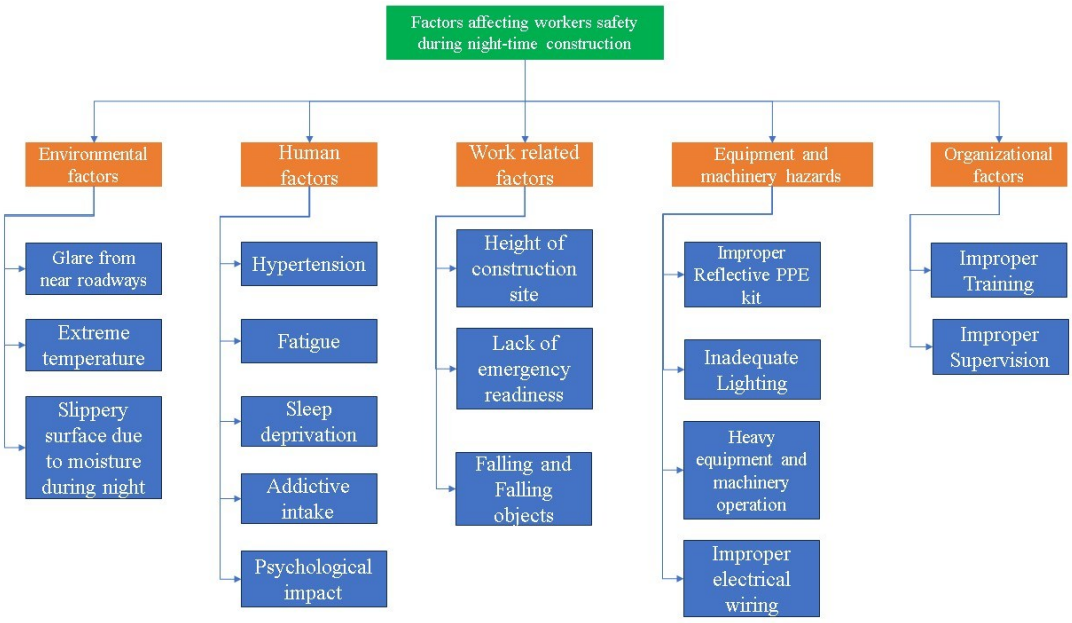

Figure 3: Hierarchical structure of AHP factors

After developing the hierarchical structure, the weights to each of the 17 items were computed with the help of the 9-point Likert scale developed by Saaty (2008). This scale is widely used in the Analytic Hierarchy Process (AHP) for pairwise comparisons. The experts related the importance of each item through a consistent framework ranging from 1 (equal importance) to 9 (extreme importance). The comparison matrix of this study takes the form of an inverse centred around the diagonal. When the values of the two factors in the matrix are 1, they have equal relative importance. In addition, the size of the comparison matrix may depend on the number of factors in the hierarchy. The AHP scale used in this study is shown in Table 3.

Table 3: Saaty's 9-point AHP scale for pairwise comparison

Scale	Definition	Explanation
1	Equally important	Both factors have the same criteria.
3	Moderately important	One criterion is slightly more important than the other.
5	Strongly important	One criterion is more important than the other.
7	Very strongly important	One criterion is far more important than the other.
9	Extremely important	One criterion is hugely more important than the other.
2,4,6,8	The median of the two scales	The median of the two scales.

4. RESULTS AND DISCUSSION

The results of the AHP analysis revealed the ranking of the five primary risk dimensions based on their overall impact on worker safety during nighttime construction. As shown in Table 4, work-related factors received the highest priority (weight = 0.353), followed by equipment and machinery hazards (0.286), organizational factors (0.242), environmental factors (0.070), and human factors (0.049).

Table 4: Relative importance and priority of risk dimensions identified through AHP analysis

Code	Dimension	Weight	Priorities
C	Work-related	0.353	1
D	Equipment and machinery hazards	0.286	2
E	Organisational	0.242	3
A	Environmental	0.070	4
B	Human	0.049	5

The criticality of the factor is justified by the fact that there is a much higher chance of slips. It falls during nighttime construction when there is inadequate lighting, particularly in areas with uneven surfaces or elevation changes (Chan et al., 2008). The significance of hazards related to equipment, like poor lighting and improper electrical grounding, shows the technical issues that are often overlooked during nighttime construction, especially since nighttime work and bad weather can negatively impact how well the equipment works (Arditi et al., 2005).

Furthermore, the local and global relative importance and priority measurements on items in risk factors during nighttime construction are shown in Table 5. Local weight measures a sub-criterion's relative importance within its main criterion in multi-criteria decision-making techniques such as AHP. It is obtained by comparing sub-criteria under the same category pairwise. Conversely, global weight indicates a sub-criterion's overall significance concerning the ultimate objective. It is determined by multiplying the sub-criterion's local weight by the weight of the main criterion. This aids in determining each sub-criterion's overall influence on the choice and ranking them all on a standard scale.

Table 5: Local and global priority rankings of risk attributes in nighttime construction

Dimension	Risks	Local weight	Local priorities	Global weight	Global priorities
Environmental (0.070)	A1. Impact of glare from near roadways on construction worker safety.	0.099	3	0.007	14
	A2. Influence of extreme temperatures on worker performance and risk levels.	0.537	1	0.037	7
	A3. Influence of slippery surface due to nighttime moisture.	0.364	2	0.025	9
Human (0.049)	B1. Effect of hypertension on construction worker safety.	0.102	4	0.005	15
	B2. Influence of fatigue on accident risks.	0.008	5	0.0002	17
	B3. Impact of sleep deprivation on worker efficiency and safety.	0.324	1	0.016	10
	B4. Risks associated with addictive intake during night shifts.	0.293	2	0.014	11
	B5. Psychological effects of night shift work on construction safety.	0.199	3	0.009	13
Work-related (0.353)	C1. Safety concerns are due to the height of construction sites.	0.195	2	0.069	5
	C2. Readiness and effectiveness of emergency response at night.	0.717	1	0.253	1
	C3. Risks associated with falling and falling objects in nighttime construction.	0.088	3	0.003	16
Equipment and Machinery hazards (0.286)	D1. Proper usage and potential risks of reflective PPE kits.	0.042	4	0.012	12
	D2. Impact of inadequate lighting on construction site safety.	0.235	2	0.067	6
	D3. Safety risks are associated with operating heavy machinery (cranes, hoists) in low visibility.	0.104	3	0.029	8
	D4. Hazards are due to the improper grounding of electrical wiring at construction sites.	0.619	1	0.177	2
Organisational (0.242)	E1. Adequacy of training programs for nighttime construction hazards.	0.500	1	0.121	3
	E2. Effectiveness of supervision during night shifts to ensure safety compliance.	0.500	1	0.121	3

Table 5 provides a more granular breakdown, showing the local and global weights of the individual attributes. Among the highest-ranked sub-criteria are the readiness and effectiveness of emergency response at night, hazards due to improper electrical grounding, and training adequacy for nighttime safety. These attributes indicate a clear need for improving operational readiness and supervision for nighttime operations.

Interestingly, organizational risks, specifically inadequate training and poor supervision, ranked third, suggesting that while these factors are acknowledged as influential, they

may not be as immediately threatening as physical or environmental risks. However, this could also reflect a deeper issue within India's predominantly informal construction sector, where regulatory enforcement and structured safety programs are limited. The lower weight may indicate that such systemic challenges are normalized and therefore underestimated by practitioners.

Human factors, including hypertension, sleep deprivation, and psychological stress, were ranked lowest. This may be because their impacts are often long-term and not as directly observable as other risks. Nonetheless, chronic fatigue and mental stress have been shown to reduce alertness and decision-making ability, contributing to accidents over time (Powell & Copping, 2010). Their low ranking highlights a critical oversight in workplace safety strategies, which often focuses more on immediate risks than long-term worker health.

The high priority assigned to equipment and lighting issues, such as poor visibility and risks from machinery operation, reinforces the urgent need for infrastructure investment in lighting systems and updated equipment standards for nighttime work. For example, the significance of electrical grounding issues points to a systemic lack of technical inspections and quality control during off-peak operations.

5. CONCLUSIONS

This study presents a thorough literature review to find the risks to construction workers during nighttime construction. Twenty safety experts were interviewed to analyse the priority of each risk by conducting an AHP analysis. The study concluded that the most significant factors are work-related, equipment, safety hazards, and organisational aspects. Emergency response readiness and effectiveness at night are the most critical subfactors, highlighting the importance of a rapid response mechanism and robust emergency planning. The study advocates enhanced planning in construction sites, specialized training for workers during nighttime operations, and improved site management to ensure safety during nighttime operations. These measures will lead to safer work environments and more efficient, resilient construction practices.

The study also has some limitations, such as expert interviews were conducted on a limited sample size, which may not fully represent the insights of the global construction industry. Additionally, the Analytic Hierarchy Process (AHP) relies on subjective judgments, which may introduce bias. Real-time data observations from active night construction sites could further enhance the results.

ASSESSING ORGANISATIONAL READINESS FOR DIGITAL TRANSFORMATION: KEY ATTRIBUTES FOR INDIGENOUS SOUTH AFRICAN CONSTRUCTION FIRMS

Mayowa Adedapo Ogungbe[1], Matthew Ikuabe[2] and Clinton Ohis Aigbavboa[3]

ABSTRACT

Digital transformation is a critical driver of efficiency, competitiveness, and sustainability in the construction industry. However, the readiness of indigenous South African construction firms for digital transformation remains underexplored. This study evaluates key attributes influencing organisational readiness for digital transformation within these firms. A structured questionnaire, developed from existing literature, was distributed to construction professionals engaged in digital technologies within Gauteng Province, South Africa. Using a purposive sampling approach, 68 valid responses were obtained from a sample of 100, resulting in a response rate of 68%. Data analysis was conducted using descriptive statistical techniques to rank critical attributes for digital transformation readiness. Findings indicate that an innovation mindset is the most crucial attribute, emphasising the importance of fostering a culture of technological advancement. Leadership commitment ranked second, highlighting the necessity of strong strategic leadership. Other key enablers include sustainability focus, data-driven decision-making, and technical skills development. This study contributes empirical insights into the organisational factors shaping digital transformation in indigenous South African construction firms. It underscores the need for fostering an innovation-driven culture, reinforcing leadership commitment, and integrating sustainability into digital strategies. These results lay the groundwork for policymakers, industry participants, and researchers to create focused strategies aimed at enhancing digital transformation preparedness in the South African construction industry.

Keywords: *Digital Transformation; Indigenous Construction Firms; Organisational Readiness; South Africa; Technology Adoption.*

1. INTRODUCTION

The construction sector is experiencing a fundamental shift driven by digital technologies that improve efficiency, productivity, and sustainability (Leong et al., 2024). Digital

transformation (DT) involves the incorporation of advanced technologies such as Building Information Modelling (BIM), Artificial Intelligence (AI), the Internet of Things (IoT), and cloud computing into construction processes (Lanzolla et al., 2020). These innovations streamline project management, improve collaboration, and optimise resource allocation, making digitalisation a key factor in achieving competitiveness and operational resilience. The COVID-19 pandemic significantly hastened DT in the construction sector (Olanipekun & Sutrisna, 2021), forcing companies to adopt digital tools to enhance operational efficiency and ensure business continuity. (Kim et al., 2022). However, the successful implementation of digital transformation depends largely on a firm's organisational readiness, which is influenced by several key attributes.

Indigenous construction firms are critical to any country's infrastructure development, contributing significantly to economic growth, job creation, and urban expansion (Ofori, 2015). However, these firms face significant challenges and opportunities in their digital transformation journey. Many operate in a volatile business environment, characterised by fluctuating economic conditions, evolving regulatory frameworks, and limited access to digital infrastructure (Oko-Odion & Angela, 2025). While some firms have successfully integrated digital technologies such as BIM, automation, and cloud computing, a significant portion lags behind due to financial constraints, a shortage of skilled professionals, and resistance to change (Bandara et al., 2024; Windapo & Cattell, 2013).

According to Gillani et al. (2024), organisational readiness for digital transformation is shaped by key attributes such as technological infrastructure, workforce digital skills, financial investment, leadership commitment, and organisational culture. These attributes determine how well a firm can transition from traditional construction methods to digitalised operations. However, comprehensive studies assessing these readiness factors in indigenous South African construction firms remain scarce. Therefore, this study aims to evaluate the essential attributes required for digital transformation within indigenous South African construction firms. The specific objective is to:

- Evaluates key attributes influencing organisational readiness for digital transformation within the South African construction firms.

By filling this research gap, the study aims to equip industry stakeholders, policymakers, and business leaders with actionable strategies for improving digital readiness and fostering a competitive, digitally advanced construction industry.

2. ORGANISATIONAL READINESS FOR DIGITAL TRANSFORMATION IN THE CONSTRUCTION INDUSTRY

Digital transformation (DT) revolves around how organisations evolve through the integration of digital technologies, reshaping their operations and enhancing the value they deliver to customers (Hanelt et al., 2021). According to Konopik et al. (2022), the literature surrounding DT encompasses a wide range of knowledge areas. This diversity has resulted in the absence of a unified definition for the concept. Furthermore, according to Vararean-Cochisa and Crisan (2025), construction organisations are still adjusting to the transformations driven by digitalisation, leading to the absence of standardised protocols or clearly established frameworks for the structured and efficient adoption of new technologies.

Digital advancements are essential for the smooth progress of the construction industry. However, organisational readiness for digital transformation in the construction industry is a multifaceted concept that involves technological, strategic, cultural, and human resource dimensions (Trenerry et al., 2021). Research over the past thirty years indicates that nearly 70% of large system implementations fail to deliver their expected benefits within the planned timeline and budget. Importantly, more than 85% of these failures are not due to technological flaws but rather due to challenges in integrating human factors, gaining acceptance, and building commitment to effective utilisation (Erdogan et al., 2005). This underscores the significance of organisational readiness in digitalisation adoption. Therefore, understanding the concept of organisational readiness is crucial for ensuring successful implementation. Organisational readiness for change is inherently context-dependent and lacks a universally accepted definition. It is shaped by a combination of factors, including the organizational environment, the nature of the stakeholders involved, and the specific circumstances under which change is initiated (Tran et al., 2011). In general terms, readiness refers to an organisation's proactive initiatives to prepare for and implement change, particularly digitalisation advancements. Moreover, readiness is dynamic, fluctuating based on the organisation's initiatives and capacity to adapt (Li et al., 2022). Given its variability, it is essential to examine how organisational readiness manifests in construction firms.

An organisation’s technological readiness serves as a foundational pillar in determining an organization’s ability to initiate and sustain digital transformation (Nguyen et al., 2019). This encompasses not only the availability but also the maturity and integration of digital tools and infrastructures, such as Building Information Modeling (BIM) and Immersive Technologies (ImT), which are increasingly recognized as essential for enhancing construction management practices (Wong & Abbasnejad, 2025). However, technological capability alone is insufficient without strategic leadership to drive its implementation. Leadership readiness, characterized by visionary thinking and strategic orientation, also plays a crucial role in fostering digital transformation. Similarly, effective leaders cultivate leadership schemas including strategic, future-oriented, capability-based, and experimental thinking, which collectively guide digital initiatives and promote organizational adaptability (Galli et al., 2017).

In addition to technological and leadership readiness, cultural readiness emerges as a critical enabler of digital transformation. A culture that supports innovation, embraces change, and promotes digital adoption is vital for the successful integration of emerging technologies. Organisations that exhibit cultural orientations centered on production efficiency, task achievement, and openness to innovative construction processes demonstrate a higher propensity for digital integration (Zakariyyah et al., 2021). Human resource readiness centres on the capabilities, adaptability, and preparedness of an organization’s workforce to engage with digital transformation. Among the most frequently cited challenges in this domain is the technical skills gap, which poses a significant barrier to the successful implementation of digital initiatives. The ability of personnel to comprehend, adopt, and effectively utilize digital technologies is a critical determinant of transformation success (Cetindamar et al., 2021). Addressing this challenge requires a proactive approach, including sustained investment in employee training and development programs. Additionally, organizations must build strong data management competencies to support the integration and use of digital tools, thereby enhancing overall workforce digital literacy and operational efficiency. Collectively,

these attributes technological infrastructure, strategic leadership, and organizational culture, innovative mindset, sustainability focus, and skill development, form the core attributes that influence an organization's readiness for digital transformation.

Within the construction industry, firms encounter distinct challenges that impact their digital transformation readiness. Construction companies encounter distinct challenges stemming from the intense competition within the industry, the reliance on project-based frameworks, and the ongoing demand to efficiently control both time and costs. (Ibrahim, 2018). Readiness for digitalisation in construction firms involves an organisation's ability to plan and prepare for the adoption of digital tools, ensuring seamless integration into existing workflows (Tran et al., 2011). When firms fail to adequately prepare, they often experience resistance to change, implementation delays, and inefficient utilisation of new systems (Kamm, 2017). Hence, the need to assess the needed attributes of Indigenous South African construction organisations for effective and efficient digital transformation.

Table 1 shows a summary of reviews of the key attributes that shape organisational readiness, drawing on established theoretical and empirical studies across the domains of management, information systems, and innovation.

Table 1: Attributes for digital transformation

Attribute	Definition	Readiness Category	Academic Domain	Key Citations
Leadership Commitment	Top management's dedication to driving digital transformation initiatives.	Strategic Orientation	Management	Westerman et al. (2014); Kane et al. (2015)

Innovation Mindset	Openness to experimentation and creative problem-solving.	Strategic Orientation	Innovation Management	Chesbrough (2003); Teece (2018)

3. RESEARCH METHODOLOGY

This research utilized a meticulous design to gather dependable and pertinent data while addressing the specific contextual limitations of the study. The target group consisted of construction professionals in Gauteng Province, South Africa, who are actively involved in the adoption of emerging technologies in construction processes. Gauteng was chosen as the case study area due to its significant number of construction projects undertaken by both government and private entities, making it an appropriate setting for examining digitalisation within the construction (Ogunbayo & Aigbavboa, 2024). However, this geographical focus presents a limitation to the study's generalizability. The findings reflect the perceptions and readiness of firms operating within Gauteng and may not fully capture regional disparities or challenges experienced by indigenous construction firms in other South African provinces, such as Limpopo, Eastern Cape, or KwaZulu-Natal. These regions may differ in terms of technological infrastructure, access to skilled professionals, and the maturity of digital adoption. Therefore, caution should be exercised in applying the results to the broader South African construction industry without further comparative studies.

Data was collected using a structured questionnaire distributed via Google Forms. This questionnaire was crafted based on existing literature concerning digital transformation in the construction field. To ensure alignment between the collected data and the study's aims, a purposive sampling method was employed. A total of 100 questionnaires were sent to professionals with proven expertise in digital transformation in the construction industry. Of these, 68 completed questionnaires were returned, yielding a response rate of 68%, indicating strong interest from the target demographic and highlighting the significance of the research topic. The questionnaire utilized a five-point Likert scale, from "strongly disagree" (1) to "strongly agree" (5), to effectively capture a detailed range of perceptions regarding organisational readiness for digital transformation. The internal consistency of the survey instrument was evaluated using Cronbach's alpha, resulting in a value of 0.834. This high reliability score, surpassing the recommended threshold of 0.7 (Tavakol & Dennick, 2011), confirms the robustness and internal consistency of the measurement tool, ensuring the reliability of the data for subsequent analysis. Data analysis was conducted using the Statistical Package for Social Sciences (SPSS), version 20. Descriptive statistical techniques, including Mean and Standard Deviation, were employed to facilitate the ranking and assessment of variables while maintaining analytical rigor without imposing excessive statistical assumptions. The combination of

a robust sampling strategy, a well-structured questionnaire, and reliable analytical techniques enhances the credibility of this study's findings.

4. FINDINGS

According to the respondents' background information, 44.12% (30) of the respondents holds BSc degree, 23.53% (16) holds honours degree, 11.76% (8) holds MSc degree, 17.65% (12) hold a post-matric certificate or diploma, and 2.94% (2) hold a PhD degree. The largest group of respondents consisted of Quantity Surveyors 58.82% (40), followed by Information Technologists 14.71% (10), Construction Project Managers 20.59% (14), and Construction Managers 5.88% (4). The data also reflects the years of experience of the respondents in using digital technologies in construction processes: 55.88% (38) have 0–5 years of experience, 29.42% (20) have 5–10 years, 8.82% (6) have 10–15 years, and only 5.88% (4) have more than 15 years of experience. The results of this investigation indicate that the participants in the survey possess a substantial level of professional expertise and academic qualifications, thereby enabling them to provide valuable insights to achieve the objectives of the research effectively.

Following a comprehensive review of existing literature, this study identified a set of attributes for digital transformation. These identified attributes were then presented to the study's target respondents for evaluation based on their perceived level of agreement. Respondents rated each indicator using a 5-point Likert scale, ranging from "strongly disagree" to "strongly agree". Table 2 displays the ranking of attributes essential for digital transformation by indigenous South African construction firms, as assessed by the respondents. The table shows that the Innovation mindset ranked highest with a mean item score (MIS) of 4.45 and a standard deviation (SD) of 0.738. Leadership commitment came in second with an MIS of 4.04 and an SD of 0.953. Sustainability focus was third, with an MIS of 3.98 and an SD of 0.829. Data-driven decision-making ranked fourth with an MIS of 3.94 and an SD of 0.929. Technical skills development was fifth with an MIS of 3.93 and an SD of 1.012. Change management expertise followed in sixth with an MIS of 3.92 and an SD of 0.862. Cultural adaptability ranked seventh with an MIS of 3.87 and an SD of 0.913. Collaboration and communication placed eighth with an MIS of 3.85 and an SD of 0.919. Risk management was ninth with an MIS of 3.82 and an SD of 0.863, while the client-centric approach was tenth with an MIS of 3.76 and an SD of 0.902.

Table 2: Attributes for digital transformation for Indigenous South African construction firms

Attributes	MIS	Std.D	R
Innovation Mindset	4.45	0.738	1
Leadership Commitment	4.04	0.953	2
Sustainability Focus	3.98	0.829	3
Data-Driven Decision Making	3.94	0.929	4
Technical Skills Development	3.93	1.012	5
Change Management Expertise	3.92	0.862	6
Cultural Adaptability	3.87	0.913	7
Collaboration and Communication	3.85	0.919	8
Risk Management	3.82	0.863	9

Attributes	MIS	Std.D	R
Client-Centric Approach	3.76	0.902	10

MIS = Mean Item Score; Std.D = Standard Deviation; R = Rank

Further analysis of the respondents' rankings for key attributes necessary for digital transformation is visualised in the radar chart presented in Figure 1. This chart illustrates the mean ratings of various organisational readiness attributes, grouped into three major categories: Strategic Orientation (Blue), Technical Readiness (Green), and Cultural and Operational Readiness (Orange). The findings reveal that South African construction firms exhibit a higher degree of readiness in terms of strategic orientation, with the highest-rated attributes being Innovation Mindset (4.45), Leadership Commitment (4.04), and Sustainability Focus (3.98). These results suggest that many organisations are conceptually aligned with the vision of digital transformation and are led by leadership that supports innovation and long-term value creation. In contrast, the level of technical readiness was found to be moderate, as indicated by the ratings for Data-Driven Decision Making (3.94), Technical Skills Development (3.93), and Change Management Expertise (3.92). This suggests that while firms are beginning to adopt data-informed approaches and are investing in skill development, there are still noticeable gaps in technical infrastructure, capacity, and the processes required to fully support digital transformation. However, the most critical observation is the relatively low ratings in Cultural and Operational Readiness, with Cultural Adaptability (3.87), Collaboration and Communication (3.85), Risk Management (3.82), and Client-Centric Approach (3.76) receiving the lowest scores. These findings underscore a significant weakness in the internal culture, collaborative practices, and stakeholder alignment within South African construction firms. Such limitations may hinder the successful adoption and integration of digital tools and platforms across project teams and organisational functions.

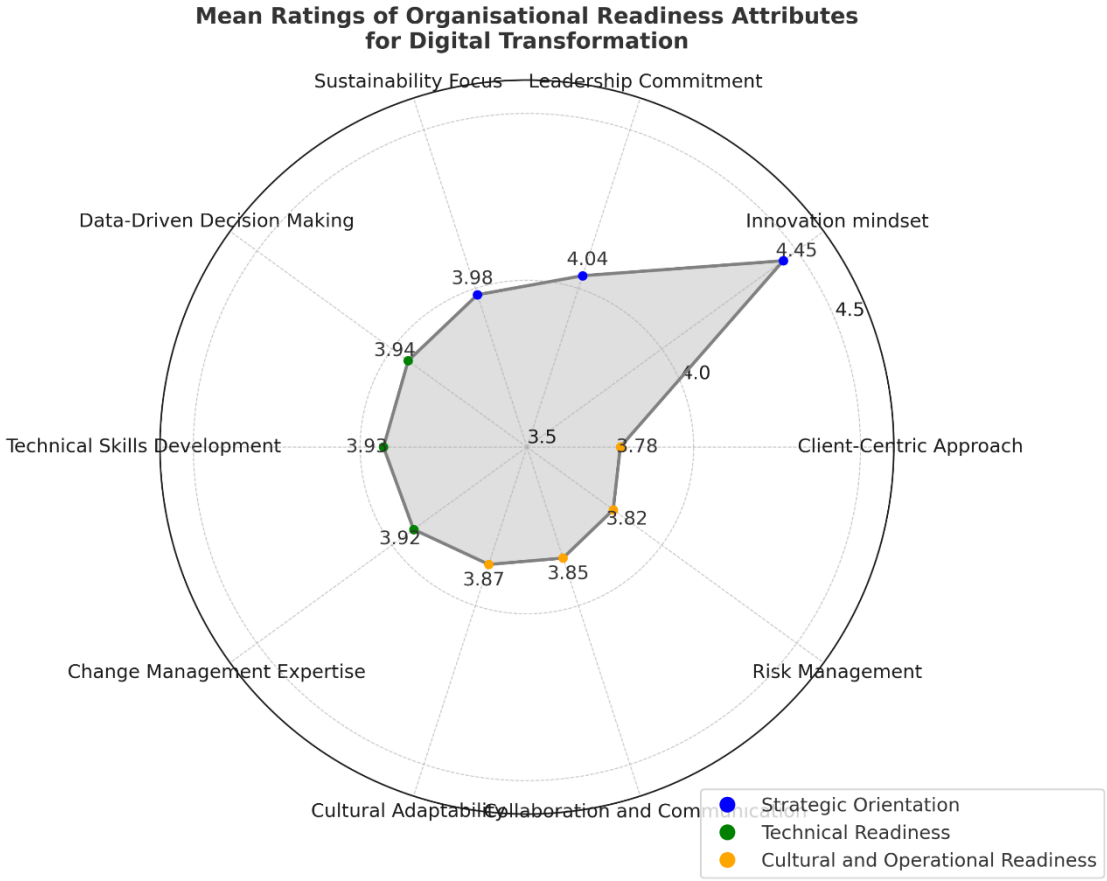

Figure 1: Attributes for digital transformation for Indigenous South African construction firms

5. DISCUSSION OF FINDINGS

The study assessed the key attributes necessary for digital transformation within indigenous South African construction firms. The results revealed that innovation mindset was ranked first, the most critical factor by the respondents, surpassing all other attributes. This finding aligns with (Demirel, 2024), who argues that an innovation mindset is an indispensable yet often invisible strategic component of digital transformation, requiring a collective commitment from leaders, employees, and organisational culture. Similarly, Joukhadar et al. (2023) demonstrated through their qualitative study that the absence of an innovation mindset amplifies the perception of complexity and uncertainty surrounding digital technologies, leading to increased technostress. Organizations that foster an innovative mindset are more capable of managing the challenges posed by digital transformation, improving their adaptability, and sustaining strategic agility in a world that is becoming increasingly digital. (Pratiwi & Justi, 2022).

The importance of leadership commitment was rated second, with MIS of 4.04 and SD of 0.953. This positions leadership commitment as the second most significant factor in driving digital transformation within indigenous South African construction firms. Leadership commitment is widely recognised as a fundamental enabler of digital transformation, as leaders set the strategic direction, allocate resources, and foster a culture that embraces technological advancements (Kane, 2019). The high MIS (4.04)

suggests that respondents view leadership as a key driver of successful digital adoption, reinforcing the argument by Hess et al. (2016) that without strong leadership, digital transformation initiatives often lack direction and fail to achieve their intended impact. According to Schiuma et al. (2022), transformational leadership is particularly crucial in guiding organisations through technological change. Leaders who are proactive, visionary, and committed to digitalisation can motivate employees, reduce resistance to change, and make sure that digital initiatives are in line with the organisation's long-term strategic objectives.

Sustainability focus, ranked third, reflects a growing trend among construction firms globally to integrate sustainability with digital transformation efforts (Kudryavtseva & Vasileva, 2021). The prioritisation of this attribute suggests that South African construction firms are becoming more conscious of the long-term advantages of adopting sustainable practices. not only for environmental outcomes but also for cost savings and regulatory compliance. This finding aligns with existing literature, which emphasises that sustainability and digital transformation are interlinked, particularly in industries like construction that have significant environmental and social impacts (Yilmaz, 2023). Furthermore, attributes like data-driven decision-making and technical skills development indicate a shift toward more strategic, informed decision-making processes as firms implement digital technologies. As suggested by Aghimien et al. (2018), data analytics and technical skills are core competencies that enhance operational efficiencies, reduce risks, and support informed project management. The implication of this result is that digital transformation in the South African construction industry is currently being driven more by strategic ambition than by operational or cultural capacity. Although there is leadership interest and a willingness to embrace innovation, the lack of cultural adaptability, weak interdepartmental communication, and underdeveloped client engagement practices may act as barriers to realising the full benefits of digital transformation.

6. CONCLUSION AND RECOMMENDATIONS

This study has provided valuable insights into the key attributes influencing digital transformation readiness within indigenous South African construction firms. The result shows that digital transformation in the South African construction industry is currently being driven more by strategic ambition than by operational or cultural capacity. Although there is leadership interest and a willingness to embrace innovation, the lack of cultural adaptability, weak interdepartmental communication, and underdeveloped client engagement practices may act as barriers to realising the full benefits of digital transformation. To address these shortcomings, stakeholders including policymakers, construction leaders, and industry training institutions should prioritise capacity-building interventions focused on organisational culture change, collaborative leadership, and human capital development. Targeted programmes such as leadership development, innovation bootcamps, cross-functional collaboration training, and digital literacy initiatives will be critical for translating strategic intentions into effective operational outcomes. By focusing on strengthening technical and especially cultural and operational readiness, the South African construction industry can position itself for a more resilient and integrated digital future. Future research should explore industry-specific challenges and opportunities related to digital transformation, ensuring a more holistic approach to technology adoption in the construction sector.

7. ACKNOWLEDGEMENTS

Special thanks to the University of Johannesburg, the SARChI Chair in Sustainable Construction Management and Leadership in the Built Environment, and the Director, Professor Clinton Aigbavboa, for their invaluable support and leadership.

ASSESSING SDG 7 PERFORMANCE: IDENTIFYING RELEVANT KPIS FOR THE SRI LANKAN CONSTRUCTION INDUSTRY

K. Thiruchelvam[1] and D.N.L.S. Uduwage[2]

ABSTRACT

The construction industry is the primary driver in achieving Sustainable Development Goals (SDGs), especially SDG 7 – affordable and clean energy. However, the progress towards SDG 7 in Sri Lanka is unclear, and there is not enough consideration given to the construction industry. This highlights the need for measurable indicators related to the Sri Lankan Construction Industry. Therefore, this study aims to assess the relevance of six United Nations (UN) established key performance indicators (KPIs) in achieving SDG 7 in the Sri Lankan construction industry and to examine perception among three different professional groups such as Architect, Engineer and Quantity Surveyor (QS). A quantitative research approach was adopted, and a questionnaire was administered to collect the information from industry professionals. In data analysis, the analyse of differences in perception across professional groups was done by Kruskal-Wallis and post-hoc tests based on the normality of the data. Significant differences in perception were identified regarding Access to Electricity (K1) and Renewable Capacity per Capita (K6), suggested the diverse priorities in promoting sustainable energy practices. Furthermore, Relative Importance Index (RII) was utilized to rank the KPIs. The results revealed that Renewable Capacity per Capita (K6), Renewable Energy (K3), and International Financial Flows (K5) are the most relevant KPIs, whereas Access to Clean Cooking (K2) and Access to Electricity (K1) are ranked as least important. The study highlights the KPIs that can effectively measure and accelerate SDG 7 achievements in Sri Lanka's construction industry. These findings provide a path to policymaker to guide the sustainable energy integration within the construction industry.

Keywords: *Construction Industry; Key Performance Indicators (KPIs); Sri Lanka; Sustainable Development Goals (SDGs).*

1. INTRODUCTION

According to the United Nations (1987), Sustainable Development (SD) meets current needs without compromising the ability of the future to meet its own. To promote sustainable development in a global context, the Sustainable Development Goals (SDGs) were introduced by the United Nations (UN) in 2015 (United Nations, 2015). 17 Sustainable Development Goals (SDGs) have been established with 169 targets to be achieved by 2030 (Patuelli & Saracco, 2022).

[1] Undergraduate, Department of Building Economics, University of Moratuwa, Sri Lanka, thkirushtika@gmail.com
[2] Senior Lecturer, Department of Building Economics, University of Moratuwa, Sri Lanka, nuwanthas@uom.lk

Among them, SDG 7 focuses on promoting sustainable practices related to affordable and clean energy to all (Ogunmakinde et al., 2022). Affordable and clean energy resources are essential to achieve a consolidated and stable world economy (Wijayarathne, 2023). In line with this goal, Sri Lanka has made notable progress in expanding electricity access across the country (International Energy Agency et al., 2024). Even though Sri Lanka has renewable energy options such as solar, wind, hydropower, coal and others, the country's energy sector remains heavily reliant on fossil fuels (Nijam & Nazar, 2017). This dependency has led to both economic challenges (Ministry of Energy, 2022) and environmental concerns (Velayutham, 2023). To address these issues, it is crucial to develop the government policy, increase investment (Wijayarathne, 2023), enhance the indicator system (Nhamo et al., 2020), technological advancement (Zia & Aslam, 2024) and follow other relevant sustainable practices.

Several studies have explored the relationship between SDG 7 and Sri Lanka. For instance, Nhamo et al. (2020) analysed the progress and challenges of achieving SDG 7 in South Asia, including Sri Lanka. Similarly, Zia & Aslam (2024) examined strategies to accelerate SDG 7 implementation in South and Southwest Asia, while Wijayarathne (2023) proposed policy recommendations to achieve SDG 7 in Sri Lanka by 2030. However, those studies failed to give priority to the specific sectors in Sri Lanka.

The progress towards SDG 7 has been identified globally and locally, comprising the contribution of all the sectors such as construction, manufacturing and energy production (Ogunmakinde et al., 2022). Similar to different nations, different sectors also have their own level of priority to attain SDG 7 (Patuelli & Saracco, 2022). Since the construction industry is a significant energy consumer and a key driver of national energy demand (United Nations, 2015), it is crucial to assess the achievement of SDG 7 in Sri Lanka through the lens of the construction sector.

To effectively monitor and evaluate the achievement of SDG 7, the UN has established six Key Performance Indicators (KPIs): access to electricity, access to clean cooking, renewable energy, energy efficiency and financing and investment needs (Ministry of Energy (2022). However, these general indicators do not fully reflect the energy challenges and opportunities in the construction sector. Identifying KPIs tailored to the Sri Lankan construction sector can provide a more accurate measurement framework and accelerate progress toward SDG 7.

Studies done by Watts (2024), Júnior et al. (2024), Wieser et al. (2019) and Blay Jnr et al. (2023), assess the performance of SDG 7 in the construction industry in United Kingdom (UK), Brazil, Australia and Ghana, respectively. However, there is a lack of studies that assess the performance of SDG 7 in the Sri Lankan construction industry. Therefore, this study aims to identify the KPIs related to SDG 7 in the Sri Lankan construction industry through below mention objectives.

1. Examine the variations in perception among the different professional groups regarding the KPIs related to SDG 7 in the Sri Lankan construction industry.
2. Extract the relevance of KPIs in achieving SDG 7 in Sri Lankan construction industry.

2. LITERATURE REVIEW

The United Nations (1987) defined the concept of Sustainable Development (SD) as "meeting the needs of the present without compromising the ability of future generations

to meet their own needs" (p.41). The report further provides a general direction to the public to work towards balancing social, environmental and economic factors (Júnior et al., 2024). Building on this foundation, Sustainable Development Goals (SDGs) were established with the ability to address a wide range of issues through 17 goals and 169 targets (Watts, 2024).

Among these, SDG 7 focuses on affordable and clean energy. Affordable energy refers to energy that is accessible at an affordable cost for all (Kamal et al., 2021), while clean energy refers to the energy that is produced and consumed in ways that minimize environmental impact (Elavarasan et al., 2024). Moreover, affordable and clean energy enhances living standards (Júnior et al., 2024), improves health outcomes and promote educational opportunities (Watts, 2024). Therefore, this goal is crucial in promote economic growth and reduce environmental impact while maintaining the broader sustainability objectives.

2.1 IMPORTANCE OF AFFORDABLE AND CLEAN ENERGY IN SRI LANKA

Sri Lanka relies heavily on fossil fuels to meet its energy demand, despite having limited domestic reserves of coal and natural gas (Nijam & Nazar, 2017). Therefore, the country is highly dependent on fuel imports (Caldera et al., 2023). However, Sri Lanka has several renewable energy options including solar power, wind energy, hydropower, biomass, natural gas and coal ((International Energy Agency et al., 2024)). Expanding the use of renewable energy could reduce reliance on fossil fuels.

According to the Ministry of Energy (2022), nearly half of Sri Lanka's export income is spent on importing fuel, leading to a severe economic crisis. When comparing the cost of the energy system, using renewable energy is estimated to cost about 206 billion euros by 2050, whereas relying on fossil fuels would cost much more than 290 billion euros in Sri Lanka (Caldera et al., 2023).

Beyond economic benefits, the shift to affordable and clean energy significantly reduces carbon dioxide emissions. It is expected to reduce carbon emissions by 14.5 % by 2030 in Sri Lanka (Zia & Aslam, 2024). According to research, 1% increase in clean energy usage results in 0.21% carbon dioxide emission reduction in Sri Lanka (Velayutham, 2023). Further, the author emphasized that affordable and clean energy helps mitigate climate change, improve the economy of the country through new job opportunities and enable more efficient use of land compared to fossil fuels.

Despite progress, the Sri Lankan energy sector continues to face persistent issues such as limited government incentives, supply interruptions, low private investment, and the ongoing economic crisis (Rajapaksha et al., 2024; Yahanpath et al., 2024). Nevertheless, the construction industry offers a significant opportunity to advance SDG 7 by addressing energy sustainability within its operations.

2.2 SDG 7 IN THE SRI LANKAN CONSTRUCTION INDUSTRY

The construction industry is one of the major contributors to Sri Lanka's national economy, accounting for 28% of the industrial sector's GDP (Central Bank of Sri Lanka, 2022). Therefore, it can be identified as one of the major energy consuming sectors in the country, which is approximately 40% of total energy use in global context (Chhabra & Grover, 2024).

However, the construction industry negatively impacts the environment through high energy and resource consumption (Opoku et al., 2022), land development, waste generation, biodiversity and climate change during the development (Wieser et al., 2019). With the rapid urbanization and infrastructure development, Sri Lanka is experiencing a rising demand for energy (Wijayarathne, 2023).

Given the significant sustainability impact of the construction industry, the adoption of sustainable practices is strongly recommended to reduce its high carbon footprint (Opoku et al., 2022), high energy usage and greenhouse gas emissions (Wieser et al., 2019). These influences are mitigatable through the usage of renewable energy systems and energy efficiency practices (Júnior et al., 2024; Opoku, 2022).

As a result, currently in Sri Lanka, the integration of renewable energy systems and energy efficiency practices is increasingly recognized as essential to achieve SDG 7 (Júnior et al., 2024; Opoku, 2022). Despite this recognition, the Sri Lankan construction industry faces challenges in implementing these practices, creating doubt about achieving SDG 7 successfully in Sri Lanka due to high initial capital costs, the economic crisis, and technological and regulatory barriers, among others (Rajapaksha et al., 2024; Yahanpath et al., 2024).

2.3 KPIs FOR SDG 7

Key Performance Indicators (KPIs) serve as a tool to effectively monitor and evaluate the achievement of SDGs (Kanie, 2020). These KPIs act as measurable metrics that reflect progress towards specific targets within the SDGs framework (Schokker et al., 2022).

The United Nations has established specific KPIs for each target of SDG 7, which are shown in Table 1.

Table 1: KPIs for SDG 7
Source: (International Energy Agency et al., 2024)

No	KPIs	Indicator description	Codes
1	Proportion of population with access to electricity.	Access to electricity	K1
2	Proportion of population with primary reliance on clean fuels and technology.	Access to clean cooking	K2
3	Renewable energy share in the total final energy consumption	Renewable energy	K3
4	Energy intensity measured in terms of primary energy and GDP	Energy efficiency	K4
5	International financial flows to developing countries in support of clean energy research and development and renewable energy production, including in hybrid systems.	International financial flows	K5
6	Installed renewable energy-generating capacity in developing and developed countries (in watts per capita).	Renewable capacity per capita	K6

As shown in Table 1, UN established KPIs for SDG 7 are focusing on access to electricity, access to clean cooking, renewable energy, energy efficiency and financing and investment needs.

2.3.1 Current Progress of SDG 7 in Sri Lanka

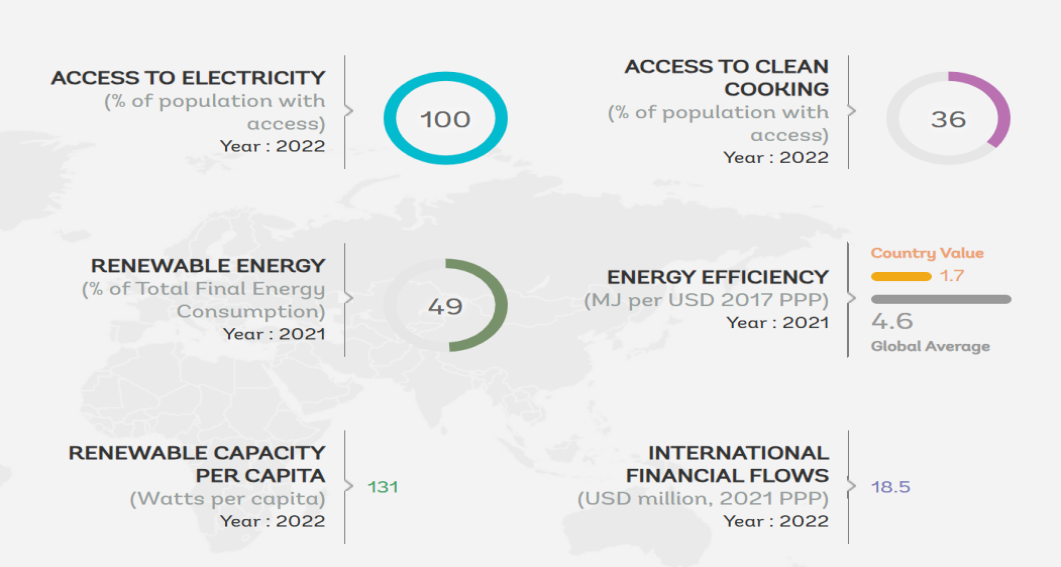

Figure 1: Current progress of SDG 7 in Sri Lanka
Source: Energy Sector Management Assistance Program (ESMAP), 2024

Figure 1 shows the progress towards SDG 7, comprising the contribution of all the sectors such as construction, manufacturing, energy production and others. Further, the progress rate indicated the necessity of accelerating progress towards SDG 7. Since the construction industry is a significant energy consumer and a key driver of national energy demand (United Nations, 2015), identifying the most relevant KPIs for Sri Lanka's construction sector and implementing targeted actions will be crucial for successfully accelerating progress toward SDG 7 in the country.

3. RESEARCH METHODOLOGY

The study adopts a quantitative research approach because it statistically analyses (Nufus et al., 2023) the perceptions of three professional groups on SDG 7's KPIs and then ranks the KPIs based on their relevance to the Sri Lankan construction industry.

The Figure 2 shows the developed research design of this study. Initially, a literature review was conducted to identify the UN established KPIs related to SDG 7. The target population of this study consists of construction professionals such as architects, engineers and quantity surveyors with knowledge on SDG 7. The sample frame is drawn from registered professionals associated with recognized organizations and industry associations such as the Green Building Council of Sri Lanka, the Institute of Engineers Sri Lanka, the Sri Lanka Institute of Architects, and other similar industry associations. Further, purposive sampling was used to get views only from people who have knowledge of research objectives (Huwae et al., 2024).

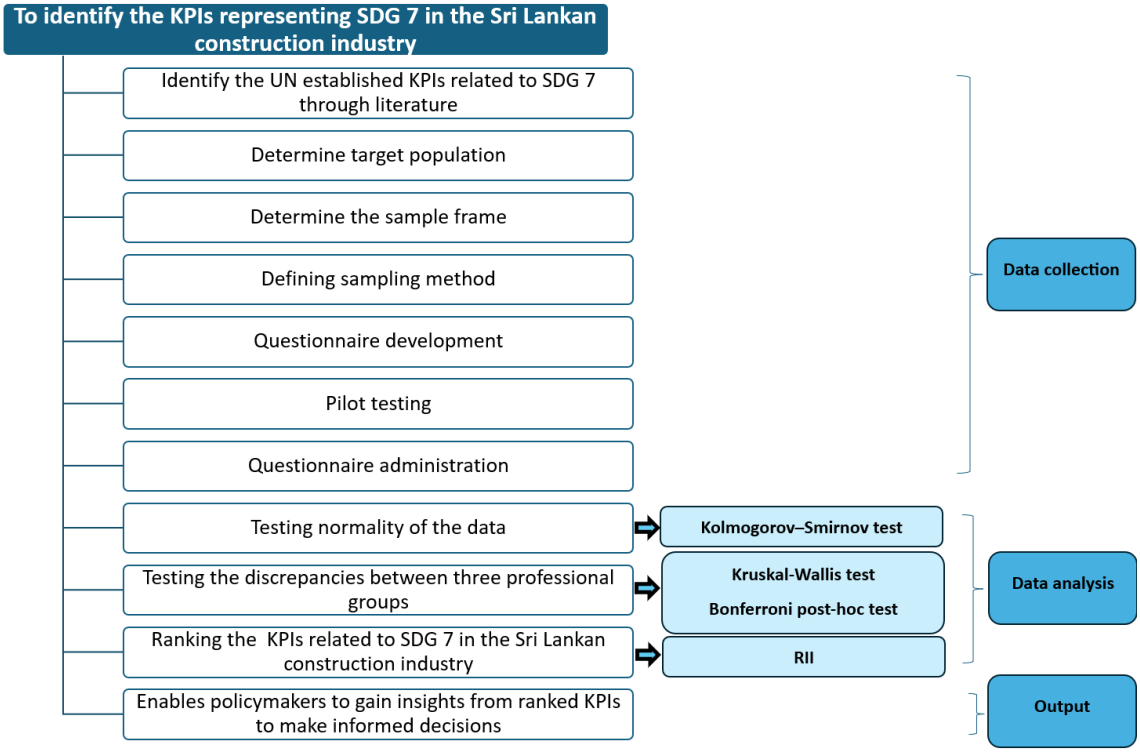

Figure 2: Research design

Since, the questionnaire survey allows data to be collected from a larger set of respondents within a shorter period (Ahmed et al., 2018), a questionnaire was administered as a data collection instrument. Before initiating the main data collection, a pilot survey was carried out among the construction industry professionals who are aligned with the sample frame. According to Ullah et al. (2023), the minimum number required for pilot testing is 20. Thus, 20 construction professionals were selected for the pilot test to check the face value of the instrument.

Following the pilot testing, a questionnaire survey was administered to 100 construction industry professionals to collect data, as it is sufficient to get a moderate response rate of 30-50% (Faleiros et al., 2016). The questionnaire consisted of 2 main sections. 1st section is used to collect the demographic information of the respondents, and 2nd section is used to gather insights into KPIs from the respondents. A 1- 5 Likert scale was utilized in the questionnaire to assess the perceived relevance of each KPI to the construction industry. The questionnaires were administered via Email, LinkedIn, and WhatsApp to enhance accessibility and encourage participation.

After the data collection, a normality test was conducted to check the normality of the data. Kolmogorov–Smirnov test was conducted to check the normality of the data as the sample size (n) > 50 (Mishra et al., 2019). Hypotheses of the Kolmogorov-Smirnov test are as follows:

- Null hypothesis (H_0): Data follows a normal distribution.
- Alternative hypothesis (H_1): Data does not follow a normal distribution.

If $p > 0.05$ the null hypothesis is accepted. Otherwise, the null hypothesis is rejected.

The Kruskal-Wallis test is a nonparametric test that does not require the data to be normally distributed (Cabral & Lucena, 2020). Since the collected data was not normally

distributed, a nonparametric test was conducted to compare the means of three specific groups: quantity surveyors, architects and engineers. Hypotheses of the Kruskal-Wallis test are as follows:

- Null Hypothesis (H_0): There is no statistically significant difference between the ideas of the groups.
- Alternative Hypothesis (H_1): There is a statistically significant difference between the ideas of the groups.

If $p > 0.05$, the null hypothesis is accepted. Otherwise, null hypothesis is rejected.

Kruskal-Wallis test only identifies that there is a different perception of the groups, but it does not specifically identify between which pair of groups the difference lies. Therefore, a post hoc test was conducted to compare pairs of groups and identify where the significant difference lies (Barriocanal et al., 2016).

- Null Hypothesis (H_0): There is no statistically significant difference between the specific pair of groups being compared.
- Alternative Hypothesis (H_1): There is a statistically significant difference between the specific pair of groups being compared.

If $p > 0.05$ the null hypothesis is accepted. Otherwise, the null hypothesis is rejected.

Even after the post hoc test, there is a possibility of having Family Wise Error Rate (FWER) in the results. To eliminate the FWER, the Bonferroni Correction method was applied (Armstrong, 2014).

After the Bonferroni Correction, if still $p < 0.05$, it ensures that the identified differences are truly significant and not due to random chance from multiple comparisons (Armstrong, 2014). Hence, there is a difference between the perceptions of the group of professionals.

3.1 RANKING KPIS

Relative Importance Index (RII) is a technique that is used to rank the factors (Azman et al., 2019). Therefore, RII is employed to rank the KPIs based on their perceived importance in achieving SDG 7 in the Sri Lankan construction industry. The formula for RII is:

$$RII = \frac{\sum W}{A \times N} \qquad \textit{(Equation 1)}$$

Where, W = weight assigned by respondents, A = highest weight on the scale and N = total number of respondents.

The KPI with the highest relative index was ranked first, while the KPI with the lowest relative index was ranked last.

4. RESULTS AND DISCUSSION

4.1 RESPONDENT'S DEMOGRAPHIC INFORMATION

For the pilot questionnaire survey, 20 pilot questionnaires were distributed, and 15 were returned with valid responses, resulting in a response rate of 75%. Subsequently, the main questionnaires were distributed to 100 construction professionals, of which 57 were returned with valid responses, achieving a response rate of 57%. According to Taherdoost & Madanchian (2024), the sufficient average response rate for business and management related studies is 51%. Both survey response rates exceed this threshold.

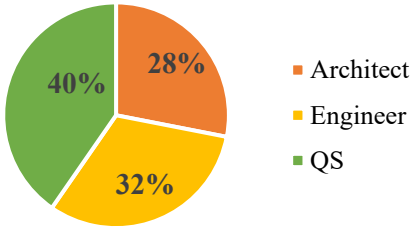

Figure 3: Respondent's profession

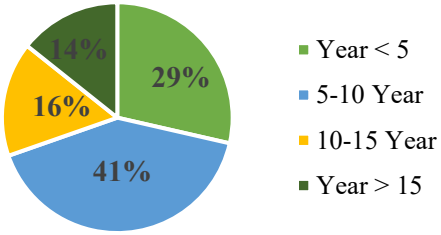

Figure 4: Respondent's experience

As shown in Figure 3, the data was collected from three categories of construction professionals such as architects, engineers, and quantity surveyors. Among the main survey respondents, the majority were Quantity Surveyors.

Further, Figure 4 illustrates the years of experience of the respondents. The average years of experience of the respondents was 11 years. All the respondents had a minimum educational qualification of a degree in a relevant field.

Moreover, as per the demographic analysis of the study, the average years of experience and minimum qualifications suggest a sufficient level of expertise and knowledge, which ensures the ability of respondents to accurately understand and respond to the questionnaire.

4.2 VARIATIONS IN PERCEPTION AMONG THE DIFFERENT PROFESSIONAL GROUPS

UN established 6 KPIs were identified, and their relevance to the Sri Lankan construction industry was evaluated through a questionnaire survey. The identified KPIs encompass access to electricity, access to clean cooking, renewable energy, energy efficiency, international financial flows and renewable capacity per capita (see Table 1).

Initially, a pilot survey was conducted to assess the clarity, relevance, and comprehensiveness of the questionnaire before its distribution for the main data collection. After the pilot survey, only a few minor changes in terminology were made to improve the clarity of the questionnaire.

The main questionnaire was then administered to construction industry professionals, and the data were collected. After data collection, the normality of the data was tested using the Kolmogorov-Smirnov test. The results of the Kolmogorov-Smirnov test are presented in Table 2.

Table 2: Normality test and Kruskal Wallis test

KPIs	Code	Kolmogorov-Smirnova test	Kruskal Wallis Test
		Sig.	Asymp. Sig.
Access to electricity	K1	0.015	0.014
Access to clean cooking	K2	0.020	0.512
Renewable energy	K3	0.000	0.605
Energy efficiency	K4	0.001	0.473
International financial flows	K5	0.001	0.310
Renewable capacity per capita	K6	0.003	0.033

According to Table 2, all significance (Sig.) values from the Kolmogorov-Smirnov test are less than 0.05 ($p < 0.05$). Thus, the null hypothesis is rejected, indicating that the data does not follow a normal distribution.

Subsequently, Kruskal-Wallis test was applied to determine whether there are differences in perceptions among these groups. Except for Access to electricity (K1) and Renewable capacity per capita (K6), all other KPIs had $p > 0.05$. This indicates that there is no statistically significant difference in perceptions among the groups regarding K2, K3, K4, and K5.

However, the Kruskal-Wallis test results showed a statistically significant difference in perceptions among the groups regarding K1 and K6. Therefore, a post hoc test was conducted to compare pairs of groups and pinpoint where the significant differences occurred. The results of the post hoc test are presented in Table 3.

Table 3: Post hoc test and Bonferroni correction

Code	Pairs of groups	Significance	Adjusted significance*
K1	Architect - Engineer	0.146	0.437
	Architect - QS	0.004	0.011
	Engineer - QS	0.157	0.470
K6	Architect - Engineer	0.010	0.029
	Architect - QS	0.094	0.283
	Engineer - QS	0.271	0.812

**Bonferroni correction*

According to Table 3, the post hoc test shows the following.

- For Access to electricity (K1), the Architect and QS pair have a discrepancy between their ideas ($p < 0.05$).
- For Renewable capacity per capita (K6), the Architect and Engineer pair has a discrepancy between their ideas ($p < 0.05$).

Even after conducting a post hoc test, the possibility of errors due to FWER remains. The Bonferroni adjustment was done to test whether the p-value of K1 and K6 becomes significant due to the FWER.

As shown in Table 3, even after Bonferroni adjustment, the significant values remain below 0.05 for the Architect and QS pair (K1) and the Architect and Engineer pair (K6).

Thus, these differences are genuinely significant and not due to random chance from multiple comparisons. This confirms that there is a difference in the perceptions of the groups of professionals. Interdisciplinary collaboration gaps within the construction industry may contribute to this variation. Construction professionals from different backgrounds often have specialized skills and knowledge unique to their respective disciplines (Faris et al., 2024). As a result, this may create varying levels of exposure towards the sustainable concepts and might influence their attitudes towards access to electricity and renewable energy integration. For instance, according to ESMAP (2024), Sri Lanka had achieved near-universal access to electricity by 2022. Since Quantity Surveyors are often involved in project costing, they may be more aware of national electrification coverage and funding compared to Architects. This may lead to differences in their perceptions regarding K1.

4.3 RELEVANCE OF KPIS IN ACHIEVING SDG 7 IN SRI LANKAN CONSTRUCTION INDUSTRY

To identify the relevance of the identified KPIs in achieving SDG 7 within the Sri Lankan Construction Industry, an assessment was carried out using the Relative Importance Index (RII) method to rank the KPIs based on their perceived significance by industry professionals. The results of the RII method are presented in Table 4.

Table 4: Relative Importance Index (RII) for KPIs

KPIs	Code	Total Weight	Relative Index	Rank
Renewable capacity per capita	K6	232	0.814	1
Renewable energy	K3	231	0.811	2
International financial flows	K5	228	0.800	3
Energy efficiency	K4	209	0.733	4
Access to clean cooking	K2	185	0.649	5
Access to electricity	K1	178	0.625	6

As shown in Table 4, RII results identified that Renewable Capacity per Capita (K6) and Renewable Energy (K3) are the most critical KPIs related to the Sri Lankan construction industry, ranking 1st and 2nd, respectively. It demonstrates the industry's attention to increasing renewable energy sources and their per capita availability. Additionally, the Sri Lankan government has launched several solar projects, such as the Thanamalwila Solar Power Project and the Wishwin Solar Energy Project, as well as wind energy projects like the Westgate Wind Power Project and the Wind Will Wind Power Project, to promote renewable energy adoption in the country (Sri Lanka Sustainable Energy Authority, 2025). These initiatives may have influenced industry professionals to prioritize renewable energy-related KPIs. In contrast, Access to Electricity (K1) was ranked the lowest, illustrating less attention towards this KPI from the Sri Lankan construction industry. According to ESMAP (2024), Sri Lanka has already achieved near universal access to electricity. As electricity access is nearly complete, construction professionals may have ranked this KPI the lowest, shifting their focus toward renewable energy expansion and energy efficiency improvements.

The RII ranking results show alignment with global trends, where countries prioritize energy goals based on their specific needs and development status. For instance, developed nations such as Germany, UK, Iceland, Sweden and others prioritize renewable energy expansion (Climate Council, 2022). In contrast, countries like Nigeria and Kenya focus on increasing electrification rates in their energy policies (International Energy Agency et al., 2024). Sri Lanka, despite being a developing country, is aligning with global sustainable energy practices due to its existing electricity coverage and increasing focus on clean energy solutions. These results highlight the importance of identifying KPIs based on a country's economic context, policy frameworks, and existing energy infrastructure.

5. CONCLUSION

In Sri Lanka, the construction industry significantly contributes to national development while being a major energy consumer. This highlights the importance of integrating SDG 7, which promotes affordable and clean energy, into the sector. To support this effort, the present study identified six key performance indicators (KPIs) in achieving SDG 7 within the Sri Lankan construction industry and explored variations in perception among different professional groups, such as architects, engineers and QSs. Understanding the difference between perceptions is important since professionals play different roles in the design, planning and implementation of construction projects, their influence in the integration of sustainable energy practices may vary. The findings revealed that there is a significant difference in perception among the professionals regarding Access to Electricity (K1) and Renewable Capacity per Capita (K6). The notable differences in perception between Architects and QSs for Access to electricity (K1) and between Architects and Engineers for Renewable capacity per capita (K6) suggest the varying priorities of different professional groups in advancing sustainable energy practices. Furthermore, ranking the KPIs helps prioritize areas of focus for improving SDG 7 performance in the Sri Lankan construction sector. As per RII results, Renewable Capacity per Capita (K6) and Renewable Energy (K3) are identified as the most relevant KPIs for the Sri Lankan construction industry, securing the 1st and 2nd positions, respectively. Conversely, Access to Clean Cooking (K2) and Access to Electricity (K1) were ranked the least important (5th and 6th), suggesting that these aspects receive relatively less attention within the industry. However, the study was limited to 6 KPIs identified by the UN, excluding other locally relevant indicators. Identifying more targeted, construction industry-specific indicators could enhance the precision of progress measurement. This presents a direction for future research to expand the KPI scope and compare findings across other developing countries. Moreover, the study contributes to academic knowledge by filling the gap in research on SDG 7-related KPIs within the Sri Lankan construction industry, and to industry practice by supporting accelerated progress toward SDG 7 through the implementation of these KPIs and by informing policymaking.

ASSESSING THE IMPACT OF ORGANISATIONAL CULTURE ON DIGITAL TRANSFORMATION IN THE SRI LANKAN FACILITIES MANAGEMENT INDUSTRY

A.S.W. Karunarathna[1] and Jayantha Wadu Mesthrige[2]

ABSTRACT

Amid rapid global technological advancements, the Facilities Management (FM) profession has undergone a significant transformation. Digitisation has emerged as a key driver in improving the efficiency, organization, and sustainability of physical infrastructure. Practitioners often perceive digital transformation beyond mere technological adoption, emphasizing the need for organizational change and strategic alignment to fully realize its benefits. This paper aims to analyse the impact of organisational culture on the digitalisation of FM functions in the Sri Lankan FM industry. To achieve the objective, this study employed a quantitative methodology using a survey approach. Data were collected through a questionnaire administered to a sample of 51 respondents[3] from the FM industry. Eight hypotheses were tested using a t-test to examine the impact of cultural dimensions on the digitalisation in FM functions. The findings indicate that organisational culture has a significant impact on the digitalisation of the FM functions. Specifically, factors such as, hierarchical structure, leadership support and advocacy, risk acceptance, cross-department collaboration, employee empowerment, learning and skill development, flexibility and the influence of subcultures were found to positively affect the digitalisation. Conversely, change management practices were not found to have a significant impact. This study makes a novel contribution by addressing an important gap in the existing literature, specifically, underexplored intersection of organizational culture and digitalization within the FM sector, an area that has received limited scholarly attention despite its growing relevance in the digital era.

Keywords: *Digitalisation; Facilities Management; Hypothesis Testing; Organisational Culture; T-Test.*

1. INTRODUCTION

The rapid evolution of digital technologies has significantly transformed the competitive dynamics of industries. While new technologies are driving digitalisation even in sectors traditionally dependent on physical value proposition, they also create new opportunities for businesses' growth (Hartl & Hess, 2017). Digital transformation has made a significant change in how firms operate and interact with their customers, partners, and

[1] Lecturer (on Contract), Department of Facilities Management, University of Moratuwa, Sri Lanka, sandunik@uom.lk
[2] Senior Lecturer, School of PCPM, RMIT University, Australia, wadu.jayantha@rmit.edu.au

staff, and it entails using digital technologies to develop new business models, increase efficiency, improve consumer experience, and gain a competitive advantage (Karawya, 2024). The introduction of digitalization has resulted in a significant shift in organizational culture, which includes the collective values, beliefs, attitudes, and rituals that determine a company's identity (Deep, 2023). In today's rapidly evolving market, it is critical for businesses to recognise how organisational culture influences the shift toward digitalisation (Deep, 2023). Digital transformation initiatives are prevalent throughout industries yet often experience failure due to inert organizational cultures preventing changes (Hartl & Hess, 2017). A comprehensive strategy that considers factors like flexibility, change management techniques, ongoing evaluation, knowledge acquisition, interdepartmental cooperation, and organisational culture is necessary for effective digital transformation (Deep, 2023; Karawya, 2024). However, the impact of organisational culture on digitalisation has not received sufficient attention in existing literature, in the facilities management industry (Bozkus, 2024; Karawya, 2024; Pradana et al., 2022). Given the limited research specifically addressing the intersection of digitalization and organizational culture in the facilities management sector, this study aims to address this gap by exploring how organisational culture influences the success of digital initiatives. The paper begins with an introduction to the study, followed by a literature review on digitalisation in the FM industry, organisational culture and the impact of organisational culture on digitalisation. It then outlines the research methodology, with the final section presenting the study's conclusion.

2. LITERATURE REVIEW

2.1 DIGITAL TRANSFORMATION IN FACILITIES MANAGEMENT

Digital transformation in FM is an inherent driver in the development of contemporary infrastructural practice. With unprecedented technological advancement occurring in the global context, the profession of FM has also witnessed a radical transformation with the inclusion of digitisation as a key driver for enhancing the organization and sustainability of physical infrastructures (Rane, 2023). The complex field of FM, a profession with numerous dimensions, is situated at the intersection of this paradigm. It is responsible for the flawless operation and optimisation of heterogeneous built environments. FM encompasses a collection of technological interfaces, operational management, and strategic methods that are designed to optimise, maintain, and manage the performance of the physical environment (Lindkvist et al., 2019). In this scenario, the integration of digital technologies emerges as a revolutionary force, redefining established strategies and unleashing unique opportunities for improved efficiency, sustainability, and innovation (Yaqot & Al-Ramadan, 2024).

Key technologies driving this transformation include Building Information Modelling (BIM), the Internet of Things (IoT), Artificial Intelligence (AI), and Digital Twins (DT), which facilitate real-time data integration and predictive maintenance (Hakimi et al., 2024; Schmitter et al., 2024). According to Opoku & Lee (2022), these technologies enable FM professionals to optimise energy usage, reduce operational costs, enhance occupant comfort, and ensure compliance with safety and sustainability standards. Despite these advantages, the digital transformation of FM poses several challenges. These include a shortage of skilled personnel, high initial investment costs, data privacy concerns, and resistance to change within traditional FM structures (Vimak et al., 2023).

For successful digital adoption, organizations must invest in skill development of the workers, change management strategies, and robust digital infrastructure.

2.2 KEY DIMENSIONS OF AN ORGANISATIONAL CULTURE

Organisational culture is a critical component of operation that influences the efficiency and efficacy of the organisation (Sap, 2021). Organizational culture refers to the shared values, beliefs, norms, and practices that influence the behaviour of individuals within an organisation. It is defined as the set of shared values that a group holds, which shapes how it understands, proposes, and responds to its surroundings (Tadesse & Debela, 2024). Culture of an organisation can be identified through its symbols, rituals, language, and artifacts unique to an organization. According to Cameron & Quinn (2006), there exists four primary types of organizational culture: clan (team-oriented culture), adhocracy (innovative culture where accepts risk), market (competitive and results oriented), and hierarchy (structured and controlled). A strong organizational culture aligns employee behaviours with strategic goals, enhancing performance and productivity (Tadesse & Debela, 2024), while also fostering employee engagement, satisfaction, and retention (Denison & Mishra, 1995).

The culture within organisations is the primary focus of organisational culture dimensions (Tadesse & Debela, 2024). Organisational culture is assessed by researchers using a variety of dimensions. Organisational culture was assessed in certain studies using workplace interactions, norms, and beliefs. Yip et al., (2020) asserted that the fundamental principles of an organisation can be perceived as internal norms and beliefs that influence behaviour. Values and norms are associated with group beliefs and customs regarding the significance of specific behaviours, work methods, and/or how to respond to change, as per Ouellette et al. (2020). Organisational value encompasses innovation, outcome orientation, collaboration, and attention to detail, as stated by Baird et al. (2018). Additionally, Binder (2016) emphasises the importance of environmental sustainability, community service, and innovation in the ethos of non-profit organisations. Furthermore, Belay et al. (2023) investigated cultural dimensions, including innovativeness, adaptability, collaboration, and ethical orientation. Table 1 demonstrates the key cultural dimensions cited by different scholars in their studies.

Table 1: Key cultural dimensions

Dimension	Description	Reference
Norms and beliefs	Group beliefs and customs regarding the significance of specific behaviours	(Yip et al., 2020)
Innovation	Acceptance of innovative ideas and support towards innovations.	(Baird et al., 2018; Binder, 2016; Ouellette et al., 2020)
Responses to change	How openly and quickly an organization and its members adapt to and support organizational transformation efforts	(Alshammari et al., 2024; Azeem et al., 2021; Ouellette et al., 2020)
Cross-Collaboration	Extent to which different departments and teams work cohesively to achieve shared goals	(Baird et al., 2018; Horvey & Moloi, 2024; McNett, 2015; Ouellette et al., 2020)

Dimension	Description	Reference
Adaptability	Organization's ability to respond to internal and external environmental changes through innovation.	(Belay et al., 2023)
Risk acceptance	The degree to which an organization encourages risk-taking and experimentation without fear of failure.	(Bosire & Kinyua, 2022; Fedotova et al., 2024; Horvey & Moloi, 2024)
Hierarchical structure	Clarity and rigidity of authority levels and decision-making processes	(Bencsik, 2024; Bosire & Kinyua, 2022; Fedotova et al., 2024; McNett, 2015)
Learning and skill development	Organization invests in employee education, upskilling, and continuous learning.	(Bencsik, 2024; Rostain, 2021; Suifan, 2021)
Employee empowerment	Autonomy and decision-making power are delegated to employees at various levels.	(Alshammari et al., 2024; Azeem et al., 2021; Bencsik, 2024; Bosire & Kinyua, 2022)
Flexibility	Organization's openness to change in roles, procedures, and strategies.	(Belay et al., 2023; Rostain, 2021)
Leadership support	Leaders actively foster a supportive environment.	(Moreno-Monsalve et al., 2021; Suifan, 2021)

2.3 ORGANIZATIONAL CULTURE AND DIGITAL TRANSFORMATION IN FACILITIES MANAGEMENT

Organizational culture plays a critical role in either enabling or obstructing digital transformation in FM, a field that increasingly relies on smart technologies, data analytics, and automation to enhance efficiency, sustainability, and user experience. Practitioners often perceive digital transformation beyond mere technological adoption, emphasizing the need for organizational change and strategic alignment to fully realize its benefits (Moreno-Monsalve et al., 2021). Organizational culture that comprises a cultural environment of flexibility, ongoing learning, and openness for change allows the incorporation of digital technologies (Alshammari et al., 2024; Fahmi, 2024). Organizational culture is then a success or failure determinant of digitalization as it affects the attitudes, communication, and executions of technological change among employees. An innovative, learning, flexible, and communicative culture provides an environment in which digital transformation is embraced rather than opposed (Fahmi, 2024). In such cultures, workers will be more willing to experiment with new tools, adapt to evolving digital workflows, and collaborate across departments behaviors that are essential to integrating technologies like artificial intelligence, cloud computing, and automation into the core business processes (Hakimi et al., 2024; Vimak et al., 2023). Conversely, rigid, risk-averse, or hierarchical organizations may be plagued by resistance to change, slow uptake, and inability to realize the complete potential of digital tools due to fear, unfamiliarity, or lack of leadership support (Hakimi et al., 2024).

Furthermore, cultural factors including employee empowerment, leadership endorsement, and interdepartmental collaboration significantly influence the rapidity and efficacy with which digital initiatives are implemented (Horvey & Moloi, 2024). When

organizational leaders actively support digital initiatives and designate resources for both training and infrastructure, this behaviour conveys a strong commitment and mitigates uncertainty among personnel (Bencsik, 2024). Further to the author, a culture that emphasizes learning, prioritizing the advancement of skills and innovation, guarantees that employees maintain adaptability and proficiency in response to digital disruptions. Ultimately, digitalization is not just a technical shift but a cultural one its success depends largely on whether the organization's culture aligns with the principles of agility, experimentation, and forward-thinking.

In the Sri Lankan FM industry, organisations exhibit a rigid and resistant culture towards technological adaptation, as revealed by Peiris et al. (2024). According to them, Sri Lankan FM organisations are characterised by several cultural deficiencies, including lack of strategic level involvement, delayed adoption of technology, insufficient knowledge and experience and a lack of skills in implementing technological solutions. As an example of a proactive and innovative culture, FM practitioners in developed regions such as Hong Kong emphasize leadership and technology competencies (Peiris et al., 2024). Sri Lankan FM organisations, by contrast, often operate within hierarchical structures and place greater emphasis on routine service activities and cost control (Rajini & Kaluarachchi, 2019). According to Weerasinghe and Sandanayaka (2013b, 2013a), traditional and relationship-based management styles are often reinforced in Sri Lankan FM integration practices, largely due to organisational factors such as ownership type and closeness of client relationships. FM service consistency is further affected by cultural factors such as poor communication, limited decision-making autonomy, and significant employee turnover (Herath et al., 2019). These characteristics indicate a culture that struggles to adjust to rapid technological changes, highlighting the critical importance of studying digitalisation within the industry. Compared to Sri Lankan FM, the construction and hospitality industries exhibit a higher level of digital maturity, largely due to their more supportive organisational cultures. Driven by innovation-oriented leadership and collaborative work environments, construction firms often adopt technologies such as BIM (Chathuranga et al., 2025). Similarly, the hospitality industry is characterised by customer-centric and adaptive cultures, reflected in its adoption of digital tools such as AI and IoT (Muwandeniya & Eranda, 2022). On the other hand, Sri Lankan FM organisations remain constrained by their lack of digital readiness, limited strategic involvement, and rigid hierarchical structures (Peiris et al., 2024). Insights of these sectors clearly indicate that the FM industry in Sri Lanka must undergo significant cultural transformations to enable successful digitalisation.

3. METHODOLOGY

Aiming to analyse the impact of organisational culture on the digitalisation of the FM functions in the Sri Lankan FM industry, this study adopts a quantitative methodology using a survey-based approach. Using a convenience sampling method, a sample of 51 professionals from the FM industry was selected based on their accessibility and availability to the researcher. The target group comprised individuals/professionals directly involved in or affected by digital transformation within the FM sector, particularly those with relevant insights into organizational culture and change. A questionnaire survey was developed and administered based on insights from existing literature. It comprised two sections: demographic information of the participants and the impact of cultural dimensions on digitalisation. The organisational culture of the

respondents was assessed based on their flexibility in adopting new initiatives and their acceptance of innovations, reflecting their level of digital maturity. Likert style rating questions, using a five-point scale, were used to elicit respondents' opinions of the impact of each nominated variable. The scale intervals are interpreted as follows:

1 = Strongly Disagree
2 = Disagree
3 = Neither Agree nor Disagree
4 = Agree
5 = Strongly Agree

Based on the collected data, hypothesis was developed to assess the study's objective, and hypothesis testing was subsequently conducted. For the data analysis, SPSS v.23 software was used.

3.1 HYPOTHESIS OF THE STUDY

Drawing from the literature, the effects of organisational culture on digitalisation was assessed using 8 hypotheses formulated based on identified cultural dimensions. Although 11 dimensions were initially identified, only 8 hypotheses were developed by consolidating those dimensions that shared similar definitions and suitability to the FM industry. They are:

Hypothesis 1

$H0_1$: The organization's existing hierarchical culture does not significantly influence the adoption of digital technologies.

H1: The organization's existing hierarchical culture significantly influences the adoption of digital technologies.

Hypothesis 2

$H0_2$: The organization's leadership support and advocacy do not play a significant role in facilitating the adoption of digital technologies.

H2: The organization's leadership support and advocacy play a significant role in facilitating the adoption of digital technologies.

Hypothesis 3

$H0_3$: The organization's history of change management does not play a crucial role in the adoption of digital technologies.

H3: The organization's history of change management plays a crucial role in the adoption of digital technologies.

Hypothesis 4

$H0_4$: The organization's cross-department collaboration does not greatly influence the adoption of digital technologies.

H4: The organization's cross-department collaboration greatly influences the adoption of digital technologies.

Hypothesis 5

$H0_5$: The organization's willingness to accept risk does not significantly influence the adoption of digital technologies.

H5: The organization's willingness to accept risk significantly influences the adoption of digital technologies.

Hypothesis 6

$H0_6$: The organization's culture of continuous learning and skills development does not significantly influence the adoption of digital technologies.

H6: The organization's culture of continuous learning and skills development significantly influences the adoption of digital technologies.

Hypothesis 7

$H0_7$: The organization's approach to employee empowerment does not play a significant role in the adoption of digital technologies.

H7: The organization's approach to employee empowerment plays a significant role in the adoption of digital technologies.

Hypothesis 8

$H0_8$: The organization's flexible and adaptive subculture does not greatly impact the adoption of digital technologies.

H8: The organization's flexible and adaptive subculture greatly impact the adoption of digital technologies

3.2 T-TEST

According to Norman (2010), t-tests can be used with Likert scale data irrespective of the normality of the distribution. Since the data are in a Likert scale format, the study adopts one sample t-test with 95% confidence interval to test the hypothesis. A one-sample t-test was applied to statistically assess whether respondents' views substantially deviated from a reference point. This test is suitable for assessing whether a sample mean diverges from a specified theoretical value (Field, 2018), especially in research using perception-based survey data (De Winter & Dodou, 2010). Since the aim was not to compare between groups but to test if the mean level of agreement for each hypothesis was significantly above the reference point, the one-sample t-test provided a suitable inferential tool.

To select a t-test for hypothesis testing, two main requirements need to be fulfilled as per Kim & Park (2019).

The data should preferably conform to a normal distribution since the t-test presumes that the sample means follow a normal distribution.

An appropriate sample size is necessary. While larger sample sizes can help mitigate issues with normality due to the central limit theorem, smaller samples require careful consideration of normality. However, Kwak & Kim (2017) mentioned that if the sample size is closer to 30, the studentized sampling distribution approximates the standard normal distribution.

The t-test equation can be seen in Equation 1.

$$t = \frac{m - \mu}{\sigma/\sqrt{n}} \qquad Equation\ (1)$$

t = *Student's t-test*
m = *mean*
μ = *theoretical value*
σ = *standard deviation*
n = *variable set size*

Decision rule: Reject or accept the hypothesis. If Sig. value < 0.05, then H1 is accepted, and H0 is rejected.

4. RESULTS AND ANALYSIS

The study was conducted with 51 professionals in the Facilities Management industry to examine the impact of various cultural dimensions within organisations on the digital transformation of the FM industry. As shown in Table 2, the majority of the participants (54.9%) are from FM service-providing organisations, while 60.78% of the participants are from organisations with a moderately innovative and adaptable culture. Notably, no participants represented organisations with highly rigid and traditional cultures, and only a small portion (3.92%) were from organisations with moderately rigid and traditional cultural environments.

Table 2: Demographic data of the participants

Demographic	Overall frequency	Percentage
Experience in the FM field		
11-15 Years	4	7.84
6-10 Years	13	25.49
2-5 Years	22	43.14
Less than 2 Years	12	23.53
FM organisation type		
Consultant	5	9.80
FM service provider	28	54.90
In-house FM department	13	25.50
Technology vendor/provider for FM	5	9.80
Organisational culture (Based on Digital Maturity)		
Highly innovative and adaptable	10	19.61
Moderately innovative and adaptable	31	60.78
Neutral	8	15.69
Moderately rigid and traditional	2	3.92
Highly rigid and traditional	0	0

4.1 HYPOTHESIS TESTING

A one-sample t-test analysis was conducted with t-test value of 3.5 and 95% confidence interval to evaluate the acceptance or rejection of the developed hypothesis. The t-test value 3.5 was chosen based on the rationale that it appropriately aligns with the ordinal

nature of the scale used in the study, making it suitable for identifying meaningful differences from a neutral midpoint (Kang et al., 2005; Vieira, 2016). While 3.0 is the mathematical median of a five-point Likert scale, it signifies a purely neutral response. This study used a test value of 3.5 to represent an appropriate midpoint that differentiates neutrality from moderate agreement. This threshold enables the study to identify those who favour a positive view, as opposed to those who remain merely indifferent. Employing 3.5 as the reference point aligns with prior studies (Chyung et al., 2017; Zumrawi & Macfadyen, 2023) indicating that values slightly beyond the numerical midpoint provide a more significant distinction in the interpretation of ordinal Likert-type data.

Table 4: One sample t-test

	Test value= 3.5				
Hypothesis	**T**	**df**	**Sig. (2-tailed)**	**Mean Difference**	**Result of the test**
H1	3.749	103	.000	.308	H01 Rejected
H2	8.361	103	.000	.558	H02 Rejected
H3	1.164	103	.247	.087	H03 Accepted
H4	9.282	103	.000	.577	H04 Rejected
H5	-3.498	103	.001	-.260	H05 Rejected
H6	3.117	103	.002	.212	H06 Rejected
H7	2.218	103	.029	.154	H07 Rejected
H8	9.282	103	.000	.577	H08 Rejected

Confidence interval percentage 95%
α=0.05

Table 4 presents the results of the one-sample t-test, indicating the acceptance and rejection of the null hypothesis based on the test statistics. At the 95% confidence level, a p-value less than or equal to 0.05 indicates the rejection of the null hypothesis, leading to the conclusion that certain dimensions of organizational culture significantly impact the digital transformation of FM functions. The analysis shows that seven out of eight hypotheses led to the rejection of the null hypothesis, suggesting that these specific cultural dimensions significantly influence the digitalisation of FM functions within organisations.

- Pre-existing culture (H1)
- Leadership support and advocacy (H2)
- Cross-departmental collaboration (H4)
- Willingness to take risks (H5)
- Continuous learning and skills development (H6)
- Employee empowerment (H7)
- Flexible and adaptive subcultures (H8)

In contrast, the results indicate that the history of change management (Hypothesis 3) does not have a statistically significant effect on the digitalisation of FM functions within organisations, as the null hypothesis ($H0_3$) for this dimension was not rejected. This suggests that, within the context of this study, the history of change management as a

dimension of organizational culture may not play a significant role in driving digital transformation in the FM industry.

4.2 DISCUSSION

Organisational culture plays a key role in digitalisation by fostering openness to change and building trust, which supports digital transformation processes. The core values and beliefs that constitute various dimensions of organisational culture shape how an organisation adapts to and embraces digital change. The Sri Lankan FM industry is characterised by rigidity, resistance to technological adoption, limited strategic involvement, and low digital readiness. These issues are compounded by traditional, hierarchical structures and relationship-based management styles, which hinder adaptability and innovation (Weerasinghe & Sandanayake, 2013b, 2013a). In contrast, FM sectors in developed regions like Hong Kong prioritise leadership and technological competencies, enabling faster digital progress (Peiris et al., 2024). Similarly, the construction and hospitality industries in Sri Lanka demonstrate higher digital maturity due to more supportive, innovation-oriented cultures (Chathuranga et al., 2025; Muwandeniya & Eranda, 2022). These comparisons highlight the urgent need for cultural transformation within the Sri Lankan FM to enable effective digitalisation. Thus, this study employed a range of organisational culture dimensions to analyse their impact on the digitalisation of the functions within the FM industry.

According to the analysis, H1 (hierarchical culture) was supported based on a t-value of 3.749 at a 95% confidence interval, indicating that organisational hierarchical culture has a significant positive impact on the digitisation of its functions. This finding aligns with the conclusions of Bencsik (2024), an organisation's existing hierarchical culture, leadership role and support, continuous learning and employee empowerment all have a significant impact on the digitalisation of the organisation. Confirming the findings of Bencsik, 2024 and Moreno-Monsalve et al. (2021), H2 indicated that leadership and its supporting role have a significant impact on the digitalization of FM functions within the FM industry. Further, in comparison to Bencsik's study, this research presents a similar perspective on the roles of continuous learning and employee empowerment. H6 and H7 were evaluated with t-values of 3.117 and 2.218, respectively, at a 95% confidence level. This suggests that continuous learning and employee empowerment have a statistically significant effect on the digitalisation of FM functions. However, Alshammari et al., (2024) found that employee empowerment does not significantly impact the success of digital transformation projects, contrary to the findings of the current study, where t-test results of Hypothesis 7 led to the rejection of the Null hypothesis ($H0_7$), indicating a significant effect of employee empowerment on the digitalisation of FM functions. According to the findings of the study, hypothesis 3 demonstrates a p-value (0.247) which is greater than 0.05, accepting the null hypothesis ($H0_3$), suggesting that the organisational history of change management does not have a significant impact on digitalisation. Alshammari et al. (2024) revealed that dimensions such as support of change do not significantly impact the success of digital transformation projects, confirming the results of this study, as the t-test accepts the H0 in hypothesis 3.

Hypothesis 4 yielded t-values of 9.282 (accepting H4), indicating that an organisation's cross-departmental collaboration has a significant effect on the digitalisation of the FM functions. These findings are broadly consistent with the research by Horvey & Moloi (2024), which emphasised that effective digital transformation necessitates cross-

collaboration to manage digital implementation effectively. According to Elena & Johnson (2015) organisations that accept risk and failures have a significant adoption rate of digital tools for their operations. Confirming to that Zhao et al. (2024) explained that openness towards calculated risks, where reacting fast and adapting to challenges in the rapidly changing environment, supported adopting new technologies in the organisation. H5 supported this by rejecting the null hypothesis (H05) and confirming that willingness to take risks significantly influences the adoption of digital technologies. Lastly, Fahmi, (2024) stated that the successful implementation of digital technologies is driven by flexibility and innovativeness, which support more agile responses to market changes and facilitate faster decision-making. In line with this assertion, the results of hypothesis 8 rejected the null hypothesis, confirming that the innovativeness and flexibility of an organisation's culture have a significant impact on the digitalisation of FM functions.

With seven out of eight hypotheses (87.5%) rejecting the null and supporting the alternative hypotheses, the study provides strong evidence that organisational culture significantly influences the digitalisation of FM functions. This study offers a novel, context-specific practical directive regarding the identification of specific organisational cultural dimensions that should be prioritised when integrating digital tools into FM functions. The results, which concentrate on the Sri Lankan FM industry, indicate that successful digitalisation is considerably influenced by dimensions such as leadership support, employee empowerment, cross-departmental collaboration, and organisational flexibility. Conversely, variables such as an organization's history of change management fail to demonstrate substantial influence. These insights assist FM managers and policymakers in culturally constrained environments in identifying the most effective cultural levers to drive digital transformation.

5. CONCLUSION

This study aimed to explore the extent to which organizational culture influences the success of digitalization initiatives within the FM sector. As FM increasingly integrates digital technologies to enhance efficiency, service quality, and sustainability, the role of culture emerges as a critical factor that can either enable or hinder this transformation. To achieve the objective, eight hypotheses were developed based on relevant cultural dimensions. The study employed t-tests to empirically analyse these hypotheses, focusing on key cultural variables affecting the effectiveness of digital transformation efforts. Data were collected from practitioners within the FM industry.

The results revealed that, based on the significance values, the null hypothesis (H0) was rejected for seven of the eight hypotheses, while one hypothesis failed to reject the null hypothesis. In conclusion, the study demonstrates that organisational culture has a significant impact on the digitalisation of FM functions. In particular, factors such as hierarchical structure of the organisation, leadership support and advocacy, risk acceptance, cross-department collaboration, employee empowerment, learning and skill development, as well as the flexibility and adaptability of subcultures, play a key role in enabling digital transformation. These findings underscore the importance of fostering a culture that supports these key dimensions to successfully drive digital transformation within the FM industry.

BARRIERS AND SOLUTIONS TO ADOPTING DIGITAL TWIN IN SRI LANKAN CONSTRUCTION

H.T.T.A. Indunil[1], R.P.H.S Bandara[2] and P.H.Y. Buddhini[3]

ABSTRACT

In the Industry 4.0 era, Digital Twin (DT) technology has emerged as a key innovation, integrating physical assets with their digital counterparts to enhance coordination, safety, and cost management in construction. Despite its potential, DT adoption in construction remains limited, particularly in developing countries like Sri Lanka, due to high costs, technological barriers, and a lack of standardized integration methods. While DT has significantly improved efficiency in other sectors, the construction industry still lacks practical large-scale applications and a unified framework for implementation. This research aims to explore the applicability of DT in Sri Lankan construction projects. Moreover, semi-structured expert interviews were conducted with 7 experts to gather data. Accordingly, the literature review and insights gathered from interviews highlighted its current usage, benefits, and barriers, and proposed 8 practical solutions to facilitate broader adoption of DT in the Sri Lankan construction industry. The findings of this research are anticipated to contribute significantly to the effective integration of DT technology within the Sri Lankan construction sector. The results underscore the promising role that DT can fulfil in addressing a variety of barriers confronting the construction industry. This study not only emphasizes the critical importance of adopting Digital Twin technology but also seeks to raise awareness of its potential, thereby encouraging its utilization and ushering in a new era of innovation in the Sri Lankan construction industry.

Keywords: *Barriers; Construction Technology; Digital Twin; Sri Lanka.*

1. INTRODUCTION

In the Industry 4.0 era with the advent of digitization, Digital Twin (DT) technology is gradually becoming one of the core technologies (Li et al., 2025). DT technology, which integrates physical assets with their digital counterparts, offers high potential to address critical construction challenges by improving coordination, safety, and lifecycle cost management (Madubuike et al., 2022). The challenges faced by the construction include issues with planning, coordination, and communication, as well as safety hazards, high maintenance costs, and inefficiencies in construction processes (Shahzad et al., 2022;

[1] Graduate Civil Engineer, School of Engineering, Swinburne University of Technology, Australia, tashiniayodya99@gmail.com
[2] Senior Lecturer, Department of Civil Engineering, Sri Lanka Institute of Information Technology, Sri Lanka, hemantha.b@sliit.lk
[3] Graduate Quantity Surveyor, Department of Quantity Surveying, Sri Lanka Institute of Information Technology, Sri Lanka, phyashodhabuddhini@gmail.com

Ullah et al., 2019). Recent studies suggest that these persistent issues could be mitigated through the application of DT technologies, which have shown promise in enhancing project efficiency and real-time decision-making (Gunatilaka et al., 2021; Shahzad et al., 2022).

DT technology is an evolving concept that integrates the physical world with the digital world (Madubuike et al., 2022). A DT is an emerging technology that is seen as crucial for an organization's digital transformation. (Qamsane et al., 2021). This method allows for the creation of a virtual model of a physical asset or process that can be monitored and analysed in real-time (Madubuike et al., 2022) . Michael Grieves, formerly of the University of Michigan, is often credited with coining the term "Digital Twin" during his 2002 presentation on Product Lifecycle Management (PLM) (Qamsane et al., 2021).

'Cost' is identified as a major barrier when it comes to developing countries to the applicability of DT (Amirthavarshan et al., 2023; Geekiyanage et al., 2025). DT application in the construction industry is low compared to other industries, despite the rise of smart buildings with automated systems (Jiao et al., 2025; Madubuike et al., 2022). According to the Amirthavarshan et al., (2023) in other sectors, DT technology has been responsible for saving product development time and costs by up to 50%. Liu et al., (2024) stated the market value of DT is expected to increase from $6.9 billion in 2022 to $73.5 billion in 2027, with an average annual growth rate of over 60%. This indicates a strong growth potential for DT in the construction industry (Liu et al., 2024).

The use of DTs in the construction industry is still in its early stages, primarily involving small-scale experiments and lacking mature practical applications (Amirthavarshan et al., 2023; Tuhaise, 2023). It should be noted that the industry lacks a clear understanding of the barriers posed by technology (Amirthavarshan et al., 2023). Furthermore, there is currently no consensus among researchers and industry practitioners on standardized approaches for integrating DT processes and data-centric technologies within building and civil infrastructure projects (Sacks et al., 2020). As such, a clear research gap exists in understanding how DT technologies can be effectively adopted and adapted to the specific needs and conditions of the Sri Lankan construction sector (Gunatilaka et al., 2021). Moreover, aligning system design with stakeholder preferences ensures that proposed DT frameworks are not only technologically feasible but also aligned with operational workflows and user capacities. This aligns with global perspectives, which emphasize stakeholder-driven DT development to ensure relevance and efficiency (Revolti et al., 2024). Bandara et al., (2024) stated future research should continue exploring these areas to provide further insights and recommendations for enhancing digital adoption in the construction sector.

Therefore, this research aims to explore the applicability of implementing DT technology in construction projects in Sri Lanka, and the study's aim has been achieved by accomplishing three objectives. Accordingly, the study will investigate the current state of DT technology implementation in Sri Lanka. Then study will identify potential benefits, and barriers to DT in construction in Sri Lanka. Ultimately, the research will suggest practical steps that can be taken to overcome common barriers associated with implementing DT technology in Sri Lankan construction projects.

2. LITERATURE REVIEW

2.1 OVERVIEW OF DT

DT technology is underpinned by advanced data processing and artificial intelligence (AI) applications such as machine learning, optimisation techniques, and search algorithms to assess project performance in real time, whether the project is under construction or in operation (Akomah et al., 2020; Radzi et al., 2024). A DT consists of three integral components: the physical system, its virtual counterpart, and the communication link that synchronises the two. This linkage is enabled by technologies including cyber-physical systems, sensors, communication networks, and mobile devices (Akomah et al., 2020; Amirthavarshan et al., 2023; Madubuike et al., 2022). DT operates as dynamic simulations, leveraging digital technologies such as Geographic Information Systems (GIS), Building Information Modelling (BIM), and Internet of Things (IoT) devices to create comprehensive, real-time representations of physical assets (Amirthavarshan et al., 2023; Omrany et al., 2025). Cloud-based platforms are used for data storage and real-time data exchange, enabling system integration.(Tuhaise, 2023). According to Madubuike et al. (2022), implementing DT technology involves a six-step process: imagining opportunities, identifying a suitable process, piloting the DT, industrializing the process, scaling the twin, and monitoring and measuring.

2.2 CURRENT STATE OF DT

The use of DT technology in the construction and real estate industries has the potential to revolutionize the management of assets and projects (Attaran & Celik, 2023). The De Soysa building on Slave Island and the Rangiri Dambulla Caves are prime examples where DTs can play a crucial role. For the De Soysa building, a DT can aid in preserving its legacy amid urban development. For the Rangiri Dambulla Caves, a DT focusing on microclimatic conditions can enhance preservation efforts by predicting and mitigating environmental impacts (Kudasinghe & Jeewananda, 2024). Another one such example is the creation of the Rankoth Vehera DT. This not only illustrates how DT applications are currently used in Sri Lanka, but it also shows how transformative DT technology can be, even in developing nations, where it can move major advancements and growth, and innovation in sectors with little experience with digital technology (Buddika et al., 2022). Despite its potential, in Sri Lanka, the adoption of DTs in the construction industry lags behind more technologically advanced countries (Kudasinghe & Jeewananda, 2024).

2.3 ADVANTAGES OF DT

Amirthavarshan et al., (2023) research indicates that DT has a high potential to solve the numerous challenges in construction site progress monitoring, rather than other current technologies in use. The benefits of integrating DT into construction processes are significant (Omrany et al., 2025). According to the literature review findings, the advantages of the DT to the Sri Lankan construction industry are given in Table 1.

Table 1: Advantages of DT

Advantage	References
Enhance the design and planning	Hämäläinen (2021); Wang et al. (2025); Acampa & Pino, (2023); Melesse et al. (2021); Singh et al. (2021)

Quality assurance	Madubuike et al. (2022)

2.4 IMPACT OF DT ON KEY CONSTRUCTION INDUSTRY ISSUES

The construction industry is under growing pressure to adopt digital technologies but continues to face challenges such as system instability, technology integration difficulties, and data security concerns (Tuhaise, 2023). A major barrier to digital transformation is the disconnect between stakeholders' expectations and the perceived impact on project outcomes, with many decision-makers failing to recognize the benefits of digital tools on performance (Jiao et al., 2025). Despite these challenges, DT technology is increasingly valued not only for its technical capabilities but also for its contributions to project efficiency, predictive maintenance, cost-effectiveness, and sustainability (Geekiyanage et al., 2025)

2.4.1 Lack of Reliable and Real-Time Data

This issue can arise from outdated reporting systems, manual data collection, and insufficient technology, leading to delays in decision-making, poor communication among stakeholders, and challenges in identifying potential problems early (Nagalingam et al., 2013). The DT has emerged as a solution that can update a BIM model with real-time data to achieve cyber-physical integration (Tuhaise, 2023). With the help of this technology, real-time monitoring and analysis can help mitigate these problems by

providing accurate and timely details for informed decision-making and improved coordination (Jiao et al., 2025; Nagalingam et al., 2013; Tuhaise, 2023)

2.4.2 Inefficient Building Systems and Poor Design

It can result in high energy consumption and maintenance costs, which can be particularly challenging for low-income households and small businesses (Emmanuel, 2004). One potential solution is DT technology, which can facilitate early simulation and testing of design options, as well as enhance collaboration and communication among project stakeholders (Hämäläinen, 2021; Parvin, 2021). This contributes significantly to national sustainability goals and fosters a greener construction industry (Hämäläinen, 2021; Jiao et al., 2025)

2.4.3 Safety

Safety is an ongoing concern in Sri Lanka's construction industry, with accidents and injuries being all too common. The lack of proper safety measures and training for workers can put them at risk of injury or even death (Priyadarshani et al., 2013). DT technology enhances safety on construction sites by offering real-time hazard analysis and suggesting preventive measures (Attaran & Celik, 2023b; Wang et al., 2025). This not only improves worker safety but also boosts productivity and reduces costs linked to work-related injuries (Priyadarshani et al., 2013). Chathuranga et al., (2025) findings stated key technologies like BIM, virtual reality, augmented reality, geographic information systems, and serious games provide various construction safety applications. Combining AI with video cameras, mobile devices, and sensors, DT creates a robust safety net for the construction industry by enabling virtual site reconstruction to monitor progress and detect safety hazards or deviations from the plan (Attaran & Celik, 2023).

2.4.4 Cost

The cost of construction projects is crucial to manage across the project life cycle, as cost overruns, differences between actual and estimated costs, are a key indicator of project success (Wijekoon & Attanayake, 2012). Geekiyanage et al. (2025) findings show that DT is commonly used in the design and planning phase in Sri Lanka's construction industry, but has minimal usage in construction, operations, and none in the end-of-life phase. By adopting Whole Life Cycle Costing (WLCC) and Life Cycle Costing (LCC) approaches, DT allows professionals to simulate entire building lifecycles, from design to demolition (Boussabaine & Kirkham, 2004). This facilitates more accurate forecasting of construction and maintenance costs, helping to make more informed decisions that balance short-term budgets and long-term value (Boussabaine & Kirkham, 2004).

2.5 BARRIERS FOR DT

According to the research studies, identified four main categories of barriers have been which are Stakeholder-Oriented (Li et al., 2025; Opoku et al., 2023), Industry-Related (Bandara et al., 2023; Opoku et al., 2023), Construction-Enterprise-Related (Opoku et al., 2023), and Technology-Related Barriers (Bandara et al., 2023; Li et al., 2025; Opoku et al., 2023). According to the literature review findings, the barriers to the DT in the Sri Lankan construction industry are given in Table 2.

Table 2 : Barriers for DT

Barriers		References
Main Category	**Sub Category**	
Stakeholder-Oriented Barriers	Level of maturity and experience	Aragón et al. (2025); Amirthavarshan et al. (2023); Sacks et al. (2020); Bandara et al. (2023); Geekiyanage et al. (2025)
	Limited understanding of potential benefits	Bandara et al. (2023); Geekiyanage et al. (2025)
	Lack of organizational support	Amirthavarshan et al. (2023); Melesse et al. (2021); Bandara et al. (2023); Madubuike et al. (2022); Haron & Zafir (2025)
Industry-Related Barriers	Fragmented nature	Amirthavarshan et al. (2023); Bandara et al. (2023); Madubuike et al. (2022); Geekiyanageet al. (2025)
	Lack of standards	Wang et al. (2025); Aragón et al. (2025); Madubuike et al. (2022); Melesse et al., (2021)
	Variability of projects	Aragón et al. (2025)
Construction-Enterprise-Related Barriers	Financial barriers	Aragón et al. (2025); Amirthavarshan et al. (2023); Madubuike et al. (2022); Melesse et al. (2021); Bandara et al. (2023)
	Time constraints	Amirthavarshan et al. (2023)
	Limited infrastructure and organisational culture	Bandara et al. (2023)
	Organisational resistance to change	Geekiyanage et al. (2025)
Technology-Related Barriers	Data challenges	Wang et al. (2025); Tuhaise (2023); Madubuike et al. (2022); Aragón et al. (2025); Melesse et al. (2021)
	Model maintenance challenges	Wang et al. (2025)
	Privacy and security risks	Wang et al. (2025); Tuhaise (2023); Madubuike et al. (2022)
	Visualization limitations	Tuhaise (2023)
	Technological compatibility	Aragón et al. (2025); Bandara et al. (2023); Sacks et al. (2020)

2.5.1 Stakeholder-Oriented Barriers

Stakeholder-oriented barriers refer to challenges faced by individuals and groups in the construction industry, including a lack of knowledge and acceptance of DT, misconceptions, and differing opinions on its value and potential for projects (Sacks et al., 2020).

2.5.2 Industry-Related Barriers

Industry-related barriers are specific to the characteristics of the construction industry itself. These challenges include the complexity of construction projects, difficulties in integrating various trades and components, the static nature of building data, and challenges related to managing data and technology in a fragmented industry (Lu et al., 2020).

2.5.3 Construction-Enterprise-Related Barriers

Construction-related barriers include challenges such as funding issues, lack of government support, legal and ethical concerns, and difficulties in coordinating infrastructure spending for digital technology use (West & Blackburn, 2017). Implementing DT technology involves significant financial investment in hardware, software, and training, which can be a barrier, especially for smaller firms or projects with limited budgets (Aragón et al., 2025; Geekiyanage et al., 2025).

2.5.4 Technology-Related Barriers

Technology-related barriers in digital transformation involve challenges like systems integration, data security and scalability issues, hardware and software limitations, concerns about data quality and reliability, and the necessity for constant internet connectivity.(Marocco & Garofolo, 2021).

3. METHODOLOGY

This study adopts a qualitative research method to identify and explore the barriers and potential solutions for implementing DT in the construction industry. Data collection integrates a systematic literature review and semi-structured interviews. Seven industry professionals were interviewed, and the interviews were semi-structured and open-ended to allow participants to provide detailed perspectives and insights. Thematic analysis was used to analyse the qualitative data.

3.1 QUALITATIVE DATA ANALYSIS

Qualitative research is a method that explores human experiences and social phenomena in depth using non-numerical data like interviews and texts, and it focuses on understanding meanings and context, providing detailed insights rather than numerical analysis (Christou, 2022). Thematic analysis is a flexible and accessible method that helps researchers identify, explore, and interpret patterns or themes within rich qualitative data, providing deep insights into participants' perspectives and social phenomena (Christou, 2022; Clarke & Braun, 2017).

3.2 EXPERTISE CORE DATA ANALYSIS

Table 3 represents the demographic data analysis of the interview.

Table 3 : Expertise core data analysis

Organization firm	Profession	No. of Interviewers	Years of experience
Construction Contracting firm	Project manager (R1, R2)	2	10-15 years
	Senior Engineer (R3)	1	10-15 years

Organization firm	Profession	No. of Interviewers	Years of experience
Construction Consultant firm	Architect (R4)	1	15-20 years
	Quantity Surveyor (R5)	1	15-20 years
	Engineer (R6, R7)	2	15-20 years

4. RESULTS AND DISCUSSION

4.1 CURRENT APPLICABILITY OF DT TECHNOLOGY AMONG THE SRI LANKAN CONSTRUCTION INDUSTRY PROFESSIONALS

Despite advancements, out of 7 interviewees, 4 experts mentioned that construction projects still rely on manual methods, primarily due to limited software experience and resistance to change stemming from traditional practices, while 3 experts indicated that projects utilized automated tools. Table 4 illustrates the current applicability of different digital technologies among Sri Lankan construction industry professionals, according to the interviewers' responses.

Table 4: Current applicability of digital technologies

Digital technologies	Awareness	Practical implementation
Digital Twin	1	1
Photogrammetry	2	1
BIM	2	3
LiDAR	2	1

Among the technologies, BIM showed the highest level of practical implementation, with 3 out of 7 participants confirming its use, while 2 participants indicated awareness of it. Photogrammetry and LiDAR were each mentioned by 2 participants in terms of awareness, but only 1 participant acknowledged actual implementation in practice for each. Digital Twin technology had the lowest overall recognition, with only 1 participant mentioning awareness and 1 noting practical use, indicating it is still relatively new or unfamiliar in the Sri Lankan context.

4.2 ADVANTAGES AND BARRIERS OF DT

Tables 5 and 6 represent a detailed overview of the barriers and advantages associated with the implementation of DT technology in the construction industry, incorporating insights from both the literature review and the interview findings

Table 5: Advantages of DT

	Advantages	Literature Review	Interviewers						
			R1	R2	R3	R4	R5	R6	R7
1	Enhance the design and planning	✓	✓	✓	✓	✓	✓		
2	Improve industrial production efficiency	✓			✓		✓	✓	✓
3	Improving management efficiency	✓	✓	✓			✓		

	Advantages	Literature Review	Interviewers						
			R1	R2	R3	R4	R5	R6	R7
4	Ensuring sustainable development	✓		✓					
5	Enhanced safety	✓						✓	
6	Cost reduction	✓			✓		✓	✓	✓
7	Improve the quality of decision-making	✓			✓		✓		
8	Improve performance	✓	✓	✓	✓			✓	✓
9	Monitor energy consumption	✓						✓	✓
10	Remote monitoring	✓	✓	✓		✓	✓	✓	✓

The analysis identified twelve advantages of DT implementation. Enhancing design and planning was widely supported, while improving performance and remote monitoring received unanimous backing from all seven interviewees. Other commonly cited benefits included improved management efficiency, cost reduction, and better decision-making quality, highlighting DT's practical value in project execution. Some advantages, like enhanced industrial production efficiency and energy monitoring, were recognized by the literature and certain respondents.

Table 6:Barriers for DT technology

	Barriers	Literature Review	Interviewers						
			R1	R2	R3	R4	R5	R6	R7
1	Limited Awareness & Understanding	✓	✓	✓	✓				✓
2	Lack of Skilled Workforce	✓	✓	✓	✓	✓	✓		✓
3	Low Adoption in Small Projects	✓		✓	✓				✓
4	Technical Complexity	✓						✓	✓
5	Lack of Tools for Maintenance Phase	✓	✓	✓	✓				✓
6	Financial barriers	✓			✓		✓	✓	

A total of 15 barriers were identified through the literature review. Notably, 6 of these barriers, as shown in Table 6, were also highlighted by experts during the data collection process, indicating alignment between the literature and professional insights. The most significant barrier is limited awareness, noted by four interviewees. Nearly all sources acknowledged a lack of skilled workforce, indicating a skills gap. Low adoption in small-scale projects was mentioned by three interviewees, suggesting resource constraints for smaller firms. Technical complexity was discussed by only two interviewees. Additionally, four noted the need for better tools for the maintenance phase, while three highlighted financial barriers and cost concerns related to advanced technologies.

4.3 PRACTICAL STEPS TO FACILITATE THE IMPLEMENTATION OF DT TECHNOLOGY IN SRI LANKAN CONSTRUCTION INDUSTRY

The Table 7 outlines the proposed practical steps to overcome the barriers of digital technology, according to the interviewees.

Table 7: Proposed practical steps

	Proposed Practical Steps	Interviewers						
		R1	R2	R3	R4	R5	R6	R7
1	Awareness Campaigns	✓		✓	✓	✓		
2	Standardized Framework		✓			✓		
3	Training Programs			✓	✓	✓		
4	Pilot Projects						✓	✓
5	Regulatory Support		✓			✓		
6	Collaboration			✓				✓
7	Education and Curriculum Development				✓	✓		
8	User-Friendly Platforms	✓					✓	✓

The key recommendations included awareness campaigns to improve understanding of DT, as supported by four interviewees. Training programs and curriculum development for capacity building were emphasized by three others. R6 and R7 suggested pilot projects, while R2 and R5 called for standardized frameworks and regulatory support. R3 and R7 highlighted the importance of collaboration among stakeholders, and R1, R6, and R7 stressed the need for user-friendly platforms to enhance adoption.

Figure 1 illustrates the suggested practical steps that can be taken to overcome common barriers associated with implementing DT technology in Sri Lankan construction projects.

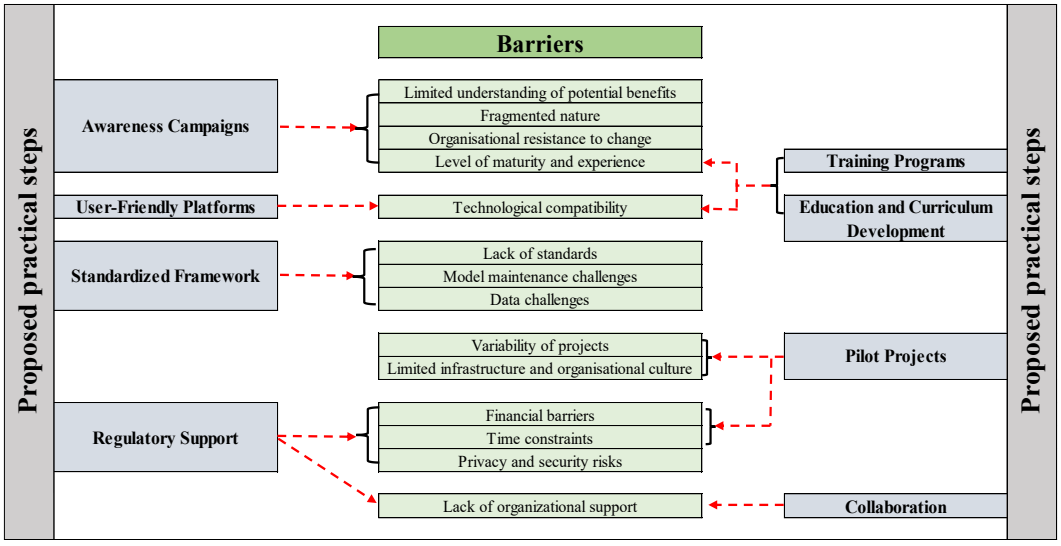

Figure 1 - Proposed practical applications to overcome the barriers of DT technology

Incorporating DT technologies into academic curricula equips future professionals with essential skills. This strategy promotes a culture that supports digital initiatives. A standardized framework enhances data sharing, model development, and integration, reducing fragmentation and improving interoperability, which is vital for effective DT applications. Creating user-friendly platforms encourages adoption, ensuring stakeholders engage with systems for smoother implementation and better data management. Pilot projects serve as test environments for DT solutions, helping identify issues, validate benefits, and build stakeholder confidence. Successful pilots demonstrate

viability and encourage broader investment. Government regulations can establish industry standards, provide financial incentives, and enforce security measures, lowering risks and costs while supporting digital innovation. Collaboration across government, academia, and industry fosters knowledge sharing, drives innovation, and establishes essential support systems for successful DT implementation.

5. CONCLUSIONS

This study assessed the applicability of DT technology in Sri Lankan construction projects by examining its current usage, potential benefits, and implementation barriers. It's important to recognize limitations in the research, as technology's dynamic nature may affect the generalizability of the findings. The research findings confirm that while DT remains an emerging concept in Sri Lanka, it holds considerable promise in addressing industry specific barriers, such as improving design accuracy, monitoring performance, enhancing safety, and managing LCC. Despite growing interest, the uptake of DT is hindered by limited stakeholder awareness, insufficient technical expertise, cost constraints, and lack of regulatory support. Addressing these barriers requires a multi-pronged approach, including targeted awareness programs, integration of DT concepts into academic and professional training, pilot implementations to demonstrate value, and the development of supportive policies and standardized frameworks. With proper strategic direction, Sri Lanka's construction industry can harness DT technology not only to modernize its practices but also to contribute to a more sustainable and digitally integrated future. Therefore, future research should incorporate stakeholder input to define the scope and functionalities of DT systems that best serve the practical needs of the industry.

BARRIERS FOR TIME, COST, AND QUALITY MANAGEMENT IN POLYMER MODIFIED ASPHALT ROAD CONSTRUCTION IN SRI LANKA

M.M. Nilanka[1], R.M.T.D. Rajapaksha[2], S.D. Gallage[3] and D.M.L.N. Bandaranayake[4]

ABSTRACT

Polymer Modified Asphalt (PMA) offers improved durability, reduced maintenance, and helps mitigate plastic waste, making it a sustainable alternative to conventional asphalt in road construction. The successful implementation of PMA in road construction depends on effective time, cost, and quality management. This study explores the unique challenges faced in PMA road projects in Sri Lanka by identifying specific barriers and proposing tailored strategies to improve project outcomes. Using a qualitative research approach, data were collected through expert interviews supported by a comprehensive literature review. This study is based on 12 semi-structured interviews with industry experts whose experience ranged from 4 to 15 years in road construction, including PMA applications. The findings highlight common barriers such as scheduling inefficiencies, supply chain disruptions, high material costs, and limited availability of skilled personnel. PMA-specific challenges, including temperature sensitivity, complex quality testing, and variability in material standards, were also identified. To address these, the study presents a matrix of 34 barriers and 15 strategies, including advanced planning, real-time tracking, value engineering, standardized protocols, and capacity-building programs. These strategies directly enhance project performance across all three dimensions of the Iron Triangle: time, cost, and quality. The research provides actionable insights for industry practitioners and policymakers to support the broader adoption of PMA, particularly in high-traffic and climate-sensitive regions.

Keywords: *Polymer Modified Asphalt; Project Management; Road Construction; Sustainable Infrastructure; Time-Cost-Quality.*

1. INTRODUCTION

Road infrastructure is crucial for socio-economic development, enabling access to markets, resources, and services. In the UK, road transport accounted for 91% of passenger travel and 67% of goods transport in 2008 (Gibbons et al., 2019), highlighting the global reliance on road networks. However, increasing traffic loads, climate

[4] Lecturer, Department of Building Economics, University of Moratuwa, Sri Lanka, lakshithab@uom.lk

variability, and the environmental impact of traditional materials like asphalt pose significant challenges (Segui et al., 2023). Sustainable alternatives, such as recycled materials, are emerging as cost-effective, eco-friendly solutions. One such innovation is Polymer Modified Asphalt (PMA), which incorporates polymers, often from plastic waste, to enhance pavement durability, flexibility, and resistance to distress (Polacco et al., 2015). PMA contributes to longer road life, reduced maintenance, and plastic waste reduction (Nawela & Samaranayake, 2024). Despite its benefits, successful PMA adoption requires effective time, cost, and quality management (Walker & Kumar, 2005). This study investigates PMA implementation in Sri Lanka, identifies key barriers, and proposes strategic solutions to support the country's transition toward more sustainable and resilient road infrastructure.

2. LITERATURE REVIEW

2.1 GENERIC APPLICATIONS OF ASPHALT

Asphalt is a widely used paving material, with over 90% of European pavements utilising bituminous mixtures due to their smooth surface and rapid construction (Kowalski et al., 2016). These mixtures, composed of aggregates and bitumen, are produced via Hot Mix Asphalt (HMA), Warm Mix, and Cold Mix methods, differing by temperature requirements (Liu et al., 2017). Despite their advantages, asphalt pavements face challenges such as environmental degradation and high greenhouse gas emissions, with global asphalt production emitting approximately 46.08 million tons of CO_2 in 2007 (Shamoon et al., 2022). To improve sustainability and performance, the industry is adopting recycled aggregates and polymers. Polymers, both synthetic and natural, enhance asphalt properties but pose compatibility challenges (Alghrafy et al., 2021). The use of recycled plastics in asphalt offers a dual benefit: addressing plastic waste issues and improving pavement durability (Costa et al., 2019).

2.2 POLYMER MODIFIED ASPHALT

Plastic waste poses significant environmental challenges due to improper disposal, prompting interest in recycling plastics for asphalt modification (Dwivedi et al., 2019). Recycled polymers enhance asphalt's flexibility, durability, and mechanical properties, contributing to improved pavement performance (García-Morales et al., 2004; Behnood & Modiri Gharehveran, 2019). Various polymer types, including thermoplastic elastomers and plastomers, offer distinct benefits. Incorporation methods include dry and wet mixing, with the wet method promoting better chemical bonding (Chavez et al., 2019). This sustainable approach reduces emissions, diverts waste from landfills, and proves more cost-effective than conventional bitumen, supporting environmentally friendly road construction (Magar et al., 2022; Moughari & Daim, 2023).

2.3 POLYMER MODIFIED ASPHALT APPLICATION IN SRI LANKAN ROADS

In recent years, Sri Lanka has escalated its efforts to incorporate recycled plastic into asphalt for road construction. The Asset Group of Companies pioneered this approach, using shredded waste plastics in asphalt mixes to pave a 500 m pilot road from Ratmalana to Borupana (AGC innovate, 2021). Building on that early success, a government-backed initiative launched in late 2020 began converting the growing plastic waste stream into a raw material for roads (Kodithuwakku et al., 2023). This led to the first public road

section paved with plastic-modified asphalt (Meegoda–Dampe Road, Homagama) in November 2020. The private sector also joined in 2021, Cargills partnered with AGC Innovate to resurface a Food City supermarket car park with Plastic Modified Asphalt Concrete (PMAC), consuming approximately 200,000 waste plastic bags (AGC Innovate, 2021). By 2022, the Western Province Road Development Authority signed agreements to use PMAC for provincial highways, supported by policies like compulsory plastic recycling and a forthcoming ban on single-use plastics (AGC Innovate, 2021). Recent research affirms the suitability of PMAC under local conditions, highlighting improvements in pavement strength and longevity as well as reductions in landfill waste and reliance on virgin materials (Kodithuwakku et al., 2023; Nawela & Samaranayake, 2024).

2.4 IRON TRIANGLE OF PROJECT MANAGEMENT

Project success in construction is often measured using the 'Iron Triangle' framework—balancing time, cost, and quality (Walker & Kumar, 2005). In Sri Lanka and similar developing countries, time overruns in road projects are common, making effective scheduling and monitoring essential (Mohammed, 2023). Cost management enhances resource use, minimises design changes, and reduces risks (Khan & Chan, 2023). Quality management ensures infrastructure durability, safety, and performance, reducing future maintenance needs (Kim et al., 2012). Integrating these three elements supports sustainable, resilient, and efficient road construction outcomes that align with stakeholder expectations (Wandiri & James, 2020).

2.5 TIME, COST, AND QUALITY MANAGEMENT BARRIERS IN ROAD CONSTRUCTION

Since PMA road construction is a relatively new concept, specific studies on its time, cost, and quality management challenges are limited. Hence, this study refers to barriers identified in conventional road construction projects to inform PMA applications. Literature highlights delays in material delivery, poor site management, incomplete designs, and financial constraints as common challenges (Arulvel & Widisinghe, 2022; Abeysinghe & Jayathilaka, 2022; Elamah, 2011; Khan & Chan, 2023). Ineffective stakeholder coordination, resistance to new technologies, and lack of training further affect project performance (Kim et al., 2012; El-Maaty et al., 2018). These barriers, although derived from regular road projects, provide a critical foundation to anticipate and address similar risks in PMA road construction. A detailed summary of the identified barriers and their impacts is presented in Table 1.

2.6 STRATEGIES FOR MITIGATING BARRIERS

To overcome time, cost, and quality-related barriers in road construction, existing literature on conventional road projects offers several strategies. Time-related solutions include efficient planning, risk management, and technologies like Integrated Project Delivery (IPD) and real-time tracking to minimize delays. Weather adaptation and streamlined permitting also support timely delivery (Lashof & Neuberger, 2023). Cost challenges are addressed through resource optimization, Life Cycle Costing (LCC), and lean construction to enhance value (Santos et al., 2017). Quality barriers are mitigated through assurance protocols, stakeholder engagement, and supplier agreements. These strategies, while not specific to PMA roads, provide relevant insights.

Table 1: Barriers influencing time, cost and quality management of road construction

Barriers	Impact			Sources												
	Time	Cost	Quality	A	B	C	D	F	G	H	I	J	L	M	N	P
Delay in delivery	✓	✓		✓		✓	✓	✓					✓		✓	✓
Shortage or unavailability	✓	✓		✓												✓
Construction mistakes	✓	✓	✓	✓		✓		✓								✓
Poor site management	✓	✓	✓	✓		✓		✓							✓	✓

3. RESEARCH METHODOLOGY

This study adopted a qualitative research approach to explore the barriers and strategies related to time, cost, and quality management in PMA road construction in Sri Lanka. Given the novelty of PMA technology in the country and the limited availability of experienced professionals, the qualitative approach was appropriate for capturing rich, contextual insights (Bryman et al., 2008; Ruffa & Evangelista, 2021). Semi-structured interviews were selected as the data collection method to allow flexibility in exploring emerging themes while maintaining focus on core research areas (Baxter & Jack, 2008). Respondents were selected using a convenience sampling with snowballing technique, targeting professionals with hands-on PMA experience. The final sample included 12 experts from consultancy and contracting sectors, each with over five years of general construction experience, road construction exposure, and at least one year of involvement in PMA projects. Details of the selected respondents are listed in Table 2 below.

Table 2: Profile of respondents

Respondent Code	Designation	Working Sector	Experience in Construction	Experience in Road Construction	Experience in PMA Road Construction
R1	Executive Engineer	Consultant	10	8	3
R2	Material Engineer	Consultant	8	5	1
R3	Project Manager	Contractor	12	10	5
R4	Planning Engineer	Contractor	7	6	2
R5	Executive Engineer	Consultant	6	4	2
R6	Project Manager	Contractor	8	6	2
R7	Engineer	Consultant	5	4	1

Respondent Code	Designation	Working Sector	Experience in Construction	Experience in Road Construction	Experience in PMA Road Construction
R8	Material Engineer	Contractor	9	7	3
R9	Material Engineer	Consultant	10	8	3
R10	Quantity Surveyor	Contractor	6	4	2
R11	Project Manager	Contractor	10	8	3
R12	Material Engineer	Consultant	15	12	1

Following this selection criterion ensured respondents were well-positioned to reflect on time, cost, and quality challenges in both traditional and PMA road projects. Interview data were manually analysed using manual content analysis to identify recurring patterns, themes, and strategies. This approach enabled the interpretation of varied perspectives, forming the basis for the effective implementation of PMA road projects in Sri Lanka.

4. RESULTS AND DATA ANALYSIS

This section presents findings on the use of conventional asphalt and its drawbacks, followed by the benefits of PMA. It also discusses PMA's implications on time, cost, and quality, and outlines key barriers and practical strategies identified through expert interviews to enhance implementation in Sri Lanka.

4.1 USE OF REGULAR ASPHALT CONCRETE IN SRI LANKA

4.1.1 Types and Usage Levels of Asphalt Concrete Mixes

In Sri Lanka, hot mix asphalt using 60/70 penetration grade bitumen is the predominant choice for road construction, valued for its durability and suitability for both binder and wearing courses. Industry professionals, including R1 and R5, affirm its widespread application. While hot mix asphalt remains the standard, gap-graded mixes are used for specific needs, and higher penetration grades like 80/100 are employed for applications such as bitumen emulsion production (R2). Cold mix asphalt, though less common, is essential for maintenance tasks like pothole patching, with R3 noting its practical use with CSS01 bitumen emulsion. This mix of diversity highlights the industry's flexible, performance-driven approach to material selection, optimizing durability, cost, and maintenance efficiency across Sri Lanka's road network.

4.1.2 Drawbacks of Regular Asphalt Concrete

Understanding the limitations of conventional asphalt is essential to justify the need for alternative solutions such as Polymer Modified Asphalt (PMA). These insights help frame the performance gaps that PMA technology may potentially address. Figure 1 illustrates the severity levels of selected drawbacks of conventional asphalt based on expert responses.

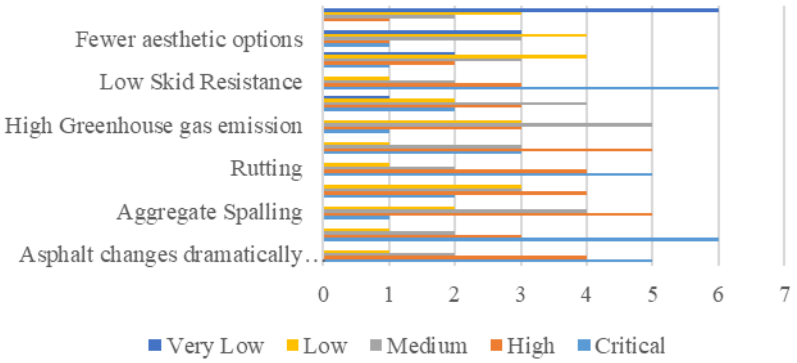

Figure 1: Impact level of drawbacks of asphalt

As shown in Figure 2, several issues are consistently rated as high or critical. "Rutting" and "Aggregate Spalling" were rated as significant challenges by multiple experts, linked to repetitive traffic loads and inadequate aggregate bonding. "High greenhouse gas emissions" and "Low skid resistance" also received medium to high concern, reflecting environmental and safety drawbacks. "Asphalt changes dramatically with temperature" emerged as a critical issue, particularly under Sri Lanka's tropical climate. Although "Fewer aesthetic options" was not widely seen as critical, the collective insights emphasize the need for enhanced materials like PMA that can overcome these performance limitations.

4.1.3 Solutions Adopted to Overcome Drawbacks of Regular Asphalt Concrete

This aimed to identify the current solutions adopted in Sri Lanka to overcome the performance limitations of conventional asphalt, as discussed in the previous section. Understanding these solutions is crucial to assess the extent to which Polymer Modified Asphalt (PMA) has been integrated into the local construction practices and to evaluate its perceived benefits relative to other alternatives. Figure 2 illustrates the various technologies currently used in Sri Lanka to address the common drawbacks of traditional asphalt, as per the respondents.

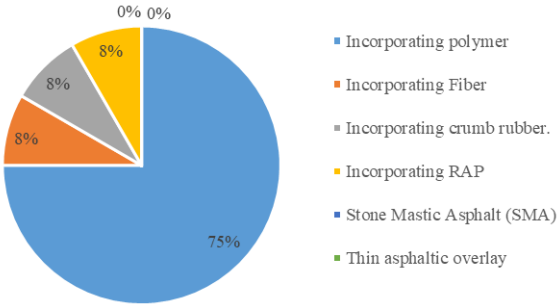

Figure 2: Solutions used in Sri Lankan context to avoid the drawbacks

As shown in Figure 3, 75% of respondents identified polymer incorporation as the primary solution adopted to enhance asphalt performance. This overwhelming preference underscores PMA's dominance in addressing issues like rutting, cracking, and aging. Other methods such as incorporating fiber, crumb rubber, and Reclaimed Asphalt Pavement (RAP) were each cited by 8% of the respondents, while Stone Mastic Asphalt (SMA) and Thin asphaltic overlays were not identified by any respondents. This trend highlights the Sri Lankan industry's strong reliance on polymer modification as the preferred performance-enhancing strategy.

4.2 USE OF POLYMER-MODIFIED ASPHALT

4.2.1 Benefits of Polymer Modified Asphalt (PMA) Usage

PMA offers significant advantages over conventional asphalt in enhancing road durability, performance, and lifespan. Traditional asphalt often suffers from rutting and fatigue cracking, particularly under heavy traffic and tropical climates. R3 highlights this, stating, "When using the penetration bitumen, several issues have occurred such as rutting and fatigue cracking," emphasizing the need for more resilient alternatives. PMA, classified under performance-grade (PG) bitumen, addresses these issues effectively. Grades such as PG 70-10 and PG 76-10, commonly used in Sri Lanka, provide superior resistance to temperature variations and mechanical stress. R9 notes that PMA requires careful temperature management during mixing, typically at 170–180°C. Despite its higher initial cost, PMA offers long-term value due to reduced maintenance and longer service life. As R11 states, "Polymer-based roads exhibit an extended estimated lifetime compared to conventional 60/70 bitumen-based roads," making PMA a reliable solution for sustainable and high-performance road infrastructure in Sri Lanka.

4.2.2 Polymer Types used for Asphalt Modification

This section examines the types of polymers used in PMA production in Sri Lanka, providing critical context to the material selection process and its implications for road performance and sustainability. Understanding the choice between virgin and recycled polymers is essential for evaluating the practical and environmental trade-offs involved in PMA usage. Figure 3 presents the proportion of virgin and recycled polymers used for asphalt modification.

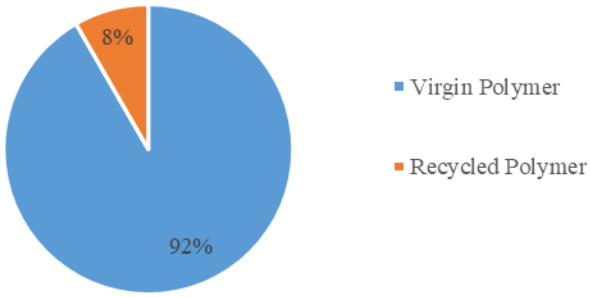

Figure 3: Polymer types used for polymer modification of asphalts in Sri Lanka

As shown in Figure 4, 92% of respondents indicated the use of virgin polymers, while only 8% reported using recycled polymers. Virgin polymers, particularly elastomers, are favoured for their consistency, flexibility, and superior performance in resisting fatigue and rutting under traffic and environmental stress. R1 highlighted that virgin polymers are preferred due to concerns over contamination in recycled materials, which affects quality and processing. However, PMA manufacturers have adopted an alternative by sourcing polymer waste directly from other manufacturers of polymer-based products. This allows access to high-quality polymer scrap free from contaminants, enabling environmental benefits by reducing landfill waste while maintaining performance standards.

4.3 BARRIERS FOR TIME, COST, AND QUALITY MANAGEMENT IN SRI LANKAN PMA ROAD CONSTRUCTION

The findings identified several unique barriers to PMA projects in Sri Lanka that arise due to the unique physical properties, handling sensitivities, and process requirements of PMA. As highlighted by respondents R1, R3, R5, R6, R8, R9, R10, and R11, the high initial cost of performance-grade bitumen and polymer additives, along with frequent price volatility, poses a major cost management barrier. Supply chain disruptions, including unreliable access to imported materials and delays in local production, often intensify these cost issues. R5 and R10 noted the temperature sensitivity of PMA during mixing and laying, which requires tight construction scheduling and coordinated material delivery to avoid cooling delays that can compromise pavement quality. In terms of quality management, R3, R6, and R9 pointed to complex and non-standardised testing protocols, as well as a shortage of trained personnel familiar with PMA technology, which negatively affects execution. Moreover, variability in testing methods and the absence of nationally standardised PMA guidelines further complicate quality assurance. The new barriers are presented in bold in Table 3 below.

4.4 STRATEGIES EMPLOYED TO OVERCOME BARRIERS IN SRI LANKAN PMA ROAD CONSTRUCTION

Key strategies include advanced planning and scheduling techniques, such as Gantt charts and critical path methods, emphasised by R6 and R10, which help anticipate potential delays and ensure timely project delivery. The integration of project management software and GPS tracking systems, highlighted by R3 and R5, enables real-time monitoring of site progress and allows for prompt decision-making to prevent schedule overruns.

Table 3: Strategies to overcome time, cost, and quality management barriers PMA road construction

Barriers	Impact			Strategy													
	Time	Cost	Quality	S1	S2	S4	S5	S6	S7	S8	S9	S10	S11	S12	S13	S14	S15	S16
Delay in delivery	✓	✓		✓	✓	✓											✓	
Shortage or unavailability	✓	✓					✓										✓

Poor direction of labour	✓	✓							✓			✓						
Poor site selection	✓	✓	✓	✓				✓										
Adverse weather	✓	✓				✓												
High cost PMAC materials	✓	✓					✓	✓		✓								
Price volatility of materials		✓					✓										✓	
Supply chain disruptions affecting PMAC materials	✓	✓		✓	✓												✓	
Temperature sensitivity during handling and laying	✓		✓	✓	✓												✓	
Material procurement delays	✓	✓		✓								✓						✓
Regulatory compliance in sensitive areas	✓										✓					✓		
Complexity in quality assurance and testing for PMAC			✓												✓			
Lack of trained personnel for PMAC technology			✓													✓		
Variability in PMAC quality standards and testing protocols			✓															

S1 – Advanced planning and scheduling
S2 – Use of project management software
S3 – Effective risk management
S4 – Accurate budgeting and forecasting
S5 – Value engineering
S6 – Collaborative contracting and strong partnerships
S9 – Align quality expectations
S10 – Process refinement and issue resolution
S11 – Regular inspections and audits to ensure compliance
S12 – Training programs and capacity-building

S7 – Continuous financial planning and regular budget reviews	S13 – Standardization of quality protocols and testing
S8 – Quality assurance and control systems	S14 – Diversification of supply sources
	S15 – Improved communication and coordination

Collaborative contracting and improved communication among contractors, consultants, and suppliers, as recommended by R8, R11, and R12, were seen as essential for achieving cost efficiencies and minimising procurement delays. Additionally, targeted training programs and capacity-building initiatives were advocated by R2, R6, and R9 to address the skill gaps in handling PMAC technologies. The need for standardised testing procedures and clearly defined quality protocols was also stressed to ensure consistent performance and regulatory compliance across projects. The strategies are mapped against the identified barriers in Table 3.

5. CONCLUSION AND RECOMMENDATIONS

Effective time, cost, and quality management is vital for the successful implementation of Polymer Modified Asphalt (PMA) in road construction, particularly in the Sri Lankan context. This study identifies the key barriers hindering PMA integration, such as temperature sensitivity during application, high material costs, supply chain disruptions, and complexities in quality assurance and presents targeted strategies to address them. The research confirms PMA's superior performance in terms of durability, flexibility, and resistance to environmental stresses, making it an optimal choice for high-traffic and climate-challenged regions in Sri Lanka.

A matrix linking 34 identified barriers to 15 practical strategies provides a comprehensive decision-support tool for practitioners and policymakers. Implications of this study include improved planning, procurement, training, and regulatory coordination, all of which can accelerate the safe and efficient adoption of PMA. However, the study is limited by its qualitative scope, reliance on a relatively small group of experts, and the current lack of long-term performance data on PMA roads in Sri Lanka. Future research should include quantitative validation, field performance monitoring, and integration of emerging technologies. Overall, this study provides critical insights for enhancing the sustainability and cost-effectiveness of Sri Lanka’s road infrastructure through optimised PMA application.

BARRIERS TO ADOPTING DIGITAL TWIN TECHNOLOGY FOR CONTRACT ADMINISTRATION IN SRI LANKAN CONSTRUCTION SECTOR

M.K.L.I.C. Fernando[1], V. Lingasabeshan[2] and P.L.I. Wimalaratne[3]

ABSTRACT

The construction industry in Sri Lanka faces growing pressure to improve sustainability, efficiency, and transparency across project lifecycles. Digital Twin Technologies (DTT) offer real-time, data-driven digital representations of construction processes, opening an avenue for enhancing contract administration practices and supporting sustainable construction. However, the implementation of DTT remains limited within the Sri Lankan context. This study investigates the organisational and technological barriers hindering the adoption of DTT for contract administration in Sri Lanka's construction sector. A qualitative research design was employed, incorporating a thematic analysis of semi-structured in-depth interviews with industry professionals. The findings reveal that key organisational barriers include resistance from organisational culture, generational divide, and skills shortages. The key technological challenges encompass cybersecurity risks, interoperability issues, infrastructure gaps, and data quality issues. Despite these constraints, the study identifies actionable insights to support DTT adoption, including variation management programs and pilot projects, Mentorship programs and hybrid workflows, university partnerships, and provides certification incentives, robust data encryption, and localized cybersecurity protocols. The paper contributes to the body of knowledge on digital innovation in contract administration and offers practical recommendations for policymakers, practitioners, and researchers seeking to foster digital transformation in emerging construction markets.

Keywords: *Barriers; Contract Administration; Digital Twin Technology; DTT; Construction Industry; Sustainable Development.*

1. INTRODUCTION

Digital Twin Technology (DTT) is an emerging innovation for developing real-time virtual models of physical systems beyond the current state of the art (Grieves & Vickers, 2016). On the other hand, Contract Administration (CA) refers to the administrative functions related to dealing with contracts including issuing instructions, managing change procedures, dealing with completion and possession issues, resolving disputes, assessing entitlement for extension of time, advising all parties of their contractual rights

[3] Lecturer, Department of Building Economics, University of Moratuwa, Sri Lanka, indraniw@uom.lk

and obligations, dealing with payment provisions, implementing contract, contract monitoring and quality assurance (QA), and contract interpretation (Davison & McCue, 2022). Nowadays, DTT is enabled in CA processes, such as compliance tracking and dispute resolution in sustainable projects. For example, DTT is used in Singaporean smart cities (Ai & Ziehl, 2024) and BIM based infrastructure monitoring in the United Kingdom (Li et al., 2019). CA in Sri Lanka remains predominantly manual, relying on paper-based documentation (Dunleavy et al., 2005), fragmented stakeholder communication via emails/ad-hoc meetings (World Bank, 2020), and reactive dispute management with 40% of projects delayed by contractual ambiguities (Hewage & Ruwanpura, 2021). BIM adoption is limited to <15% of design phases, hindering digital integration.

DTT have been repeatedly mentioned in the literature of asset management in the modern era as a conceptual enhancement (Grieves & Vickers, 2016). Using this developing body of knowledge, the current study offers empirical data on the operational integration of DTT into CA, thus re-engineering the two paradigms into a synchronised, data-driven compliance tracking and dispute resolution system. The practice of this real-time, data-driven transformation can be seen in two contexts: Singapore smart-city development and large-scale infrastructure projects in the United Kingdom (GovTech Singapore, 2022). Nevertheless, Sri Lanka's construction industry has been mostly limited to manual CA practices, fragmented stakeholder collaboration, and the lack of digital literacy (Dunleavy et al., 2005). Apart from the studies on DTT in design automation (Sobhkhiz et al., 2021) and CA with AI (Bolhassan et al., 2021), there are no previous studies regarding the DTT and CA integration in Sri Lanka. Naji et al (2024) highlighted that there are digitalization hindrances in Sri Lanka in addressing the construction issues. Thus, this study aims to identify the barriers to implementing DTT for CA processes in Sri Lanka and develop ways to overcome them.

2. LITERATURE REVIEW

2.1 WHAT IS DIGITAL TWIN TECHNOLOGY?

DTT involves creating a virtual implementation of a physical system, process, or asset that synchronises in real-time with data from sensors, Internet of Things (IoT) devices, and analytic platforms (Saad et al., 2025). By mirroring the physical entity's behaviour and lifecycle, it enables predictive modelling, simulation, and decision-making based on the entity's characteristics (Tao et al., 2018). DTT is an emerging field in the construction industry, aiming to provide solutions and improvements in various aspects of construction projects (Akanmu et al, 2019). Furthermore, DTT supports the construction industry's advancement toward the 5th industrial revolution and presents new opportunities to enhance the performance of construction projects throughout their entire life cycle (Moshood et al., 2024).

2.2 IMPLEMENTATION OF DIGITAL TWIN TECHNOLOGY FOR CONSTRUCTION CONTRACT ADMINISTRATION

DTT is useful for enhancing the contract administration in construction with transparency for monitoring, analysis, and communication, as well as enabling real-time worker and stakeholder interaction (Ammar et al., 2022). Further, Tao et al. (2018) highlighted that DTT helps to reduce risks, enhances compliance tracking, and improves the CA through real-time data sharing and automation of Workflows. For example, in Singapore smart

infrastructure project, DTT has been used to pave the ground via automated progress monitoring and claims resolution with an immutable audit trail in the aspect of designing and CA (Shishehgarkhaneh et al., 2022). DTT digitises documentation and facilitates collaboration among stakeholders, updates in a single platform that reduces ambiguities in contractual terms, and helps to hold people accountable (Tao et al., 2018).

2.3 BENEFITS OF IMPLEMENTING DTT FOR CA

Table 1 provides ten (10) key benefits of implementing DTT in construction CA with supported verifiable academic references from global case studies from the UAE, Germany, and Hong Kong. By linking each benefit (i.e., greater transparency, cost savings, and sustainability alignment) to empirical evidence, which demonstrates DTT's prevention of disputes, improving compliance, and maximising the use of available resources. These findings collectively highlight the possibility of DTT capabilities to assist CA practice by combining real-time data analytics with contractual governance to achieve efficiency and accountability in CA within projects.

Table 1: Benefits of DTT adoption

Ref	Benefit	Description	Sources
A1	Transparency	With DTT, stakeholders can have a real time access to project data and that decreases information asymmetry and increase trust. With virtual models, clients and contractors have an opportunity to collaborate in monitoring progress, compliance and resource allocation.	(Lu et al., 2020)
A2	Enhanced efficiency	Automated workflows eliminate time-wasting documentation, approval and change order cycles. AI based analytics reduces the reporting time by up to 30–40 percent in the Australian infrastructure projects.	(Alnaser et al., 2024)
A3	Mitigation of risks	Predictive analytics predict with high certainty when contractual obligations are not met (such as delay, overrun) prior and in advance of corrective action, when possible. In U.S. transportation projects, it reduced the disputes by 25%.	(Management Association, Information Resources, 2022)
A4	Alignment with sustainable development	SDG 9 and 11 are the goals supported by DTT as we optimize material use and reduce waste. In the case of UAE, real time resource tracking reduced the site waste by 18%.	(Tao et al., 2018)
A5	Enhanced collaboration	Real time collaboration is possible on cloud based DTT platforms. In Singapore, shared virtual models led to 15% reduction in rework once rework was counted, for the contractual deliverables.	(Bado et al., 2022)
A6	Cost reductions	It contributes to savings in the long term because rework and delays are reduced. German study also showed that DTT cut project overruns by 20%, by following a budget correctively.	(Serugga, 2025)

Ref	Benefit	Description	Sources
A7	Monitoring compliances	DTT automates compliance checks of contractual terms. For example, DTT was used in UK projects to enforce the sustainability certification with 100% compliance with the standard.	(Boje et al., 2020)
A8	Improved decision-making techniques	Stakeholders can evaluate scenarios (design changes), test before implementation and improve the accuracy of decisions by 35% in Japanese megaprojects.	(Pal et al., 2023)
A9	Building maintenance	Maintenance needs predictions through a lifecycle of a project can be made by DTT.	(Kaewpoonsuk, 2024)
A10	Dispute resolution activities	Immutable audit trails reduce the number of ambiguities in contractual claims.	(Gupta & Jha, 2023)

2.4 BARRIERS TO IMPLEMENTING DTT IN CA

The barriers to DTT adoption in Contract Administration (CA) identified from the literature sources are presented in Table 2. Fifteen (15) barriers were identified and categorised using thematic analysis technique. Accordingly, five groups emerged, namely technological, organisational, economic, regulatory and cultural barriers for implementing DTT in construction CA.

According to the table, key technological barriers are fragmented data integration (USA), cybersecurity risks (Australia), human and procedural limitations (India and Australia), and resistance to digitization (Sri Lanka and Australia). Further, systemic and policy related barriers are reflected in economic barriers such as high costs (South Africa) and unclear ROI (Canada), regulatory gaps (Europe), and legal ambiguities (Singapore). Therefore, the need for holistic strategies becomes stronger because cultural resistance to abandoning traditional practices is a barrier to DTT adoption that could be consistent with global best practices and local contexts. The survey of the reported global barriers to digitalisation, shown in Table 2, is exhaustive, but the existing literature shows heterogeneity in context.

Edmundson (2022) focuses on cybersecurity issues in the context of high technologies, and Çetin et al. (2021) on the problem of interoperability in regulatory fragmentation, particularly in Europe. However, existing literature does not pay much attention to interdependencies: economic limitations B10-B12, say, often compound human-capital shortages B7 in developing economies. An obvious gap is the sociotechnical analysis that would help understand the way such barriers are formed; the digital-maturity models (Kaewpoonsuk, 2022) could be used to understand why such barriers as cultural resistance B15 in Sri Lanka are rooted in systemic digital immaturity, not individual attitudes. Theoretical anchoring is required to translate lists of descriptive barriers into diagnostic tools to enable specific interventions.

Table 2: Barriers to implementing DTT

Code	Category	Barrier	Description	Global example	Source
B1	Technological	Complexity in data integration	Data formats across tools, with different data formats across BIM vs. legacy systems (fragmented formats).	Infrastructure projects in USA	(Lucchi, 2023)
B2		Cybersecurity issues	Risks related to data breaches in IoT devices and cloud platforms.	Smart cities in Australia	(Edmundson, 2022)
B3		Limitations in interoperability	Incompatibility between DTT tool and other CA tools.	Construction sector in Europe	(Çetin et al., 2021)
B4		Issues in accuracy and data quality	Getting error sensor data on virtual models.	Automotive projects in Germany	(He & Mao, 2023)
B5		Limitations in available infrastructure	No infrastructure at all for the existing IoT/sensor systems in developing regions.	Housing projects in South Africa	(World Bank, 2020)
B6	Organizational	Refusal to accept digitalization	Contractors prefer manual CA processes.	Mega projects in Sri Lanka	(World Bank, 2020)
B7		Existing skill gaps to DTT adoption	Missing professionals with the knowledge to integrate DTT and CA.	Construction firms in India	(Çetin et al., 2021)
B8		Issues in stakeholder collaboration	Silos between contractors, clients, regulators, and work functions.	Infrastructure projects in Brazil	(Hewage & Ruwanpura, 2021)
B9		Lack of team spirit and leadership support	Absence of commitment in other senior management to programs to fund DTT initiatives.	Renewable energy projects in UK	(McKinsey & Company, 2023)
B10	Economic	Higher implementation costs	Sensors, software license, training	Renewable energy projects in South Africa	(Lucchi, 2023)
B11		Minimum ROI (Return on Investment)	Uncertainty about long-term financial benefits of DTT adoption.	Smart cities in Canada	(McKinsey & Company, 2023)

Code	Category	Barrier	Description	Global example	Source
B12		Maintenance costs	Updating and maintaining DTT systems expenses	Transportation projects in USA	(Lucchi, 2023)
B13	Regulatory	Insufficient standardized frameworks	Absence of global protocols for DTT-CA integration.	Construction sector in Europe	(McKinsey & Company, 2023)
B14		Legislative uncertainties	Ambiguities in liability for DTT-generated decisions.	Smart contracts in Singapore	(World Bank, 2020)
B15	Cultural	Preference for traditional practices	Lack of willingness to stop using CA processes based on paper.	Construction contracts in Sri Lanka	(Hewage & Ruwanpura, 2021)

3. RESEARCH METHODOLOGY

Research methodology refers to the principles and procedures of logical thought processes that are applied to a scientific investigation (Fellows and Liu, 1997). Research methods, on the other hand, are merely tools. This research requires an in-depth exploration of implementing DTT technologies to improve CA. This can be achieved through examining the lived experiences of stakeholders. Qualitative methods are particularly appropriate for the capture of stakeholder views, contextual and unexpected themes (Creswell and Poth, 2018). Thus, a qualitative research approach was conducted to explore the subjective multiple barriers to DTT adoption.

Ten purposively sampled experts were interviewed using a semi-structured method, with thematic saturation reached when no new insights emerged. This methodology agrees with the rules of qualitative methodology, which do not give priority to breadth, but rather to depth, especially in the case of an expert panel that is homogeneous and explores a specialized subject (DTT-CA implementation). The collected data were analysed using thematic analysis. The analysis adopted a top-down approach, whereby pre-established themes derived from the literature synthesis initially guided the data interpretation process. Table 3 provides the profile of respondents, including their designation, years of experience, and the selection criteria for selecting them as experts for the study. The principles of ethical compliance were followed in the study. Ethics approval was sought and granted by the institution, and all the participants gave written informed consent. The data processing involved anonymization of participants and participation was voluntary. Information was stored safely to avoid unauthorized access, as it is the case with standard qualitative research procedures that involve human subjects.

Table 3: Participants' profile

Expert Code	Designation	Years of Experience	A	B	C	D
E1	Senior Quantity Surveyor	10	√	√	√	√
E2	Contract Administrator	12	√	√	√	√
E3	Commercial Manager	8	√	√	√	√
E4	Researcher	15	√	√	√	√
E5	Academic	14	√	√	√	√
E6	Construction Manager	18	√	√	√	√
E7	BIM Specialist	9	√	√	√	√
E8	Commercial Manager	11	√	√	√	√
E9	Civil Engineer	7	√	√	√	√
E10	Contract Specialist	13	√	√	√	√

A – Experience in Construction Contract Administration > 5 years

B - Awareness on DTT/ Experience on DTT

C – Minimum educational qualifications - at least a construction related degree

D - Possessing professional qualifications ‐ at least one among IQSSL, RICS, IESL, CIOB, LEED

4. FINDINGS

Even though, there were identified 15 barriers of adoption of DTT in Construction Contract Administration (CCA), the data analysis confirmed 13 critical barriers of adoption. The findings of the study uncover important pieces of information regarding the development of barriers to DTT adoption in the context of CCA in Sri Lanka. The barriers to implementing DTT for CA identified from the literature (15 barriers) were contextualized to the Sri Lankan context using in-depth interviews. Accordingly, a few barriers were modified, merged, or newly added. The research findings identified 13 barriers to implementing DTT in CA for the Sri Lankan construction industry, as outlined in Table 4. Further, the solutions were provided for the barriers through the thematic analysis of the in-depth interviews. These solutions provide actionable insights to the Sri Lankan construction industry.

From the thematic analysis of expert interviews, critical updates to the barrier framework were identified, such as the identification of new barriers and additional refinements to existing categories of barriers. According to Table 4, none of the barriers were removed from the literature findings while contextualizing to the Sri Lankan context. However, the modified barriers and newly added barriers are formatted as italicised and bolded. Thus, 6 barriers were modified by renaming, such as SLB2, SLB3, SLB4, SLB5, SLB6, and SLB7. In addition, the barriers B10, B11, and B12 have been merged as one barrier called financial constraints (SLB10). Further, the barriers B9 and B15 were merged and renamed as resistance from organisational culture (SLB9). One barrier was newly added for the SL context, specifically as vendor Lock-in (SLB13). Potential solutions for these barriers were proposed as shown in the last column of Table 4, based on the researcher's impetus and emerged from the expert discussions.

Among the 13 barriers to implementing DTT for CA in Sri Lanka, 3 barriers were overwhelmingly identified by the experts in the technological barrier category, such as cybersecurity risks, interoperability issues, and infrastructure gaps. Accordingly, the cybersecurity risks were considered most vulnerable because most firms panic about hackers accessing sensitive contract terms, as stated by E3. This was further explained by E1, recalling one of their past experiences, stating, "*the altered sensor data concealed an LKR 75 million (USD 250,000) concrete shortfall, resulting in a severe erosion of stakeholder trust in the digital system*". In further explaining, "*this incident underscores how DTT's data-dependent nature creates new attack vectors that malicious actors can exploit to manipulate contractual evidence*". This demonstrated the real-world consequences of cybersecurity risks. Like cybersecurity risks, equally problematic are interoperability issues in merging disparate digital ecosystems. E6 and E7 highlight the immense difficulties in reconciling different regional standards, whether combining Hong Kong's HKT specifications with the EU's ISO 19650 protocols or aligning the UK's BSI standards with international frameworks. These compatibility issues create significant friction in cross-border projects and even domestic operations using imported technologies. E4 adds that Sri Lanka's lack of a national digital engineering framework exacerbates these problems, resulting in fragmented data systems that cannot communicate effectively. Thus, the study proposes robust data encryption and localized cybersecurity protocols as the potential solution to the above two barriers. The next emphasized technological barrier is the infrastructure gap. The limitations in the electricity infrastructure in Sri Lanka were presented by E4 as follows: "*60% of rural construction sites lack stable internet connectivity fundamentally constrains real-time*

DTT functionality". These infrastructure gaps create a vicious cycle, where limited connectivity discourages DTT investment, which in turn slows digital infrastructure development. Therefore, the study proposes initiating a public-private infrastructure partnership and generating a DTT model through offline, capable methods as a solution to overcome the barrier.

In addition to the technological barrier category, the other three most stated barriers to implement DTT in SL CA in other barrier categories are financial constraints, generational divide, and skill shortage. When considering the financial constraints, E6 and E7 highlighted "*DTT consumes 5-7 % of project budgets in emerging markets, thus it is not unique to Sri Lanka among the competing priorities. We cannot afford it without subsidies*". Therefore, the provision of a subsidy by the government and the initiation of the adoption of the DTT model for a pre-determined phase of the construction project's CA would be the potential solutions for the barrier. Next, the resistance to technological change was pointed out by experienced professionals. This resistance is compounded by the generational divide and is significant to Sri Lanka as like financial constraints. It can be supported by a statement given by E6, *"I've used paper for 30 years—I won't trust a machine".* Adding on to that, E4 describes a pervasive attitude as *"why fix what isn't broken?".* Provision of mentorship programs for the staff of the organisation and allowing a hybrid workflow could be potential solutions to overcome the generational divide. Then, the acute skill shortage was noted as the most indicated barrier to implementing DTT in SL CA. The critical human resource limitation to implement DTT in Sri Lanka was mentioned by E5 as "*only two hundred (200) BIM-certified professionals are available nationwide in Sri Lanka*". Reinforce that statement, E7 indicated "*just 12% of local engineers have that BIM certification*". The skill gap extends beyond basic BIM competency to more advanced DTT applications, where E3 noted "*only 12% of Asian contractors have DTT-trained staff*". Thus, workforce development must accompany technological investment for successful adoption. Provision of incentives as a certification for DTT users and enhancing the partnership with the higher educational institute to incorporate the practical knowledge on DTT for construction will overcome the skill shortage to implement DTT for CA in Sri Lanka.

In addition to the above-mentioned six key barriers, there are other barriers to implementing DTT for CA in SL. Accordingly, creating protocols for sensor calibration and development of a framework for quality assurance and quality control for sensors could be a potential solution for data quality issues, which are mainly caused by errors in sensors. Further, pilot projects are suggested as solutions for the resistance that emerges from the organisational culture. Another considerable issue is the data privacy and government related barriers, where reforming the legal framework and developing laws for standardized digital evidence could be a solution. Besides, vendor-lock-in was identified as a new barrier while contextualizing the literature findings to the Sri Lankan context. E8 explained it as "*once a company chooses a specific vendor or platform to build and operate their digital twin, it becomes very difficult, expensive, or time-consuming to switch to another vendor or system later on*".

The barrier experience from this on the implementation of DTT for CA is highlighted by E9 as "*organizations may hesitate to adopt a digital twin solution if they fear they'll get locked into a system that restricts flexibility, innovation, or cost control in the future*". Therefore, the solution to this barrier, which stems from dependence on expensive proprietary software, could be to first implement the DTT in open-source DTT tools and

software. In addition, findings suggest utilizing the government-led platforms rather than those from a private vendor, which could significantly reduce the risk.

In the sociotechnical systems (STS) tradition, obstacles to the adoption of DTT are traditionally categorised into five broad categories: Technological, Organisational, Economic, Regulatory and Cultural. This schema is justified by the fact that effective implementation of DTT is based on the dynamic interplay of technological (tools, infrastructure) and social (people, structure, context) aspects (Clegg, 2000). Technological barriers (SLB1-SLB5) include shortcomings in hardware, software or connectivity as well as poor interoperability between DTT solutions. Organisational barriers (SLB6-SLB9) concentrate on the intra-firm features like capacity, cultural attitudes and governance arrangements. Economic barriers (SLB10) are based on the distribution of resources and profitability. Regulatory barriers (SLB11-SLB12) are based on external regulatory regimes that are unable to keep up with technological innovation or fail to leave legitimate policy gaps. Lastly, cultural barriers are part of organisational barriers, and they include deep-seated norms, practices and worldviews that hinder transformative change. Analytically, these classifications are helpful in that they allow the development of interventions that are specific to the subsystem that needs to be remediated; technical solutions can be designed to overcome technological barriers, and policy reform can be designed to overcome regulatory barriers. As a result, the framework provides both practitioners and scholars with a consistent, holistic view of DTT-CA adoption, softened by the realization that resistances are complex.

Technological barriers (SLB1-SLB5) were the most common, and the cybersecurity risks were the most significant constraint because of such incidents as maliciously altered sensor data that can create significant financial damage and reduce the trust of the population. Infrastructure deficiencies were also acute, with 60% of rural construction sites having no stable internet connection, thus fundamentally restricting the real-time capability of DTT.

The solutions to these technological problems are the creation of local cybersecurity standards and the creation of public-private partnerships that will modernize infrastructure. Organizational and cultural barriers (SLB6-SLB9) pointed to a significant generational gap, i.e., the reluctance of veteran professionals to digital workflows (e.g., I used paper all my life, I am not going to trust a machine), as well as to acute skills gaps, such as the fact that there are only 200 Building Information Modelling (BIM) certified professionals in the entire country. In this regard, suggestions include hybrid processes and industry incentives relating to university certification programs.

Economic and regulatory impediments (SLB10-SLB12) revolved around financial constraints, with DTT taking up 5-7 % of total project costs, encouraging firms to adopt a phased approach to adoption, with specific subsidies. The issue of data privacy highlighted the necessity of legal reforms that would help to standardize digital evidence. Vendor lock-in (SLB13) presented a new obstacle, as the use of proprietary software limited flexibility. The corresponding mitigation strategy suggests developing open-source platforms led by the government.

The current discussion contextualizes empirical results in the existing literature in a systematic way. It supports the diagnosis of Edmundson (2022) of cybersecurity vulnerabilities in high-tech environments with the measurement item SLB2 (Cybersecurity Risks). Simultaneously, it complements the work of Çetin et al. (2021)

regarding the interoperability by recognizing Vendor Lock-in (SLB13) as a poorly studied economic limitation in emerging economies. In addition, The Generational Divide (SLB6) situates the cultural barriers described by Hewage and Ruwanpura (2021) within the systemic digital immaturity of the Sri Lankan context, thus expanding the focus beyond the personal attitudes and questioning the direct transferability of global North models. The argumentation that follows hence establishes the need of sociotechnical ecosystem adaptations.

Moreover, the inclusion of potential solutions transforms Table 4 from purely diagnostic to prescriptive. The link between the barriers and proposed potential solutions is presented in the following Figure 1.

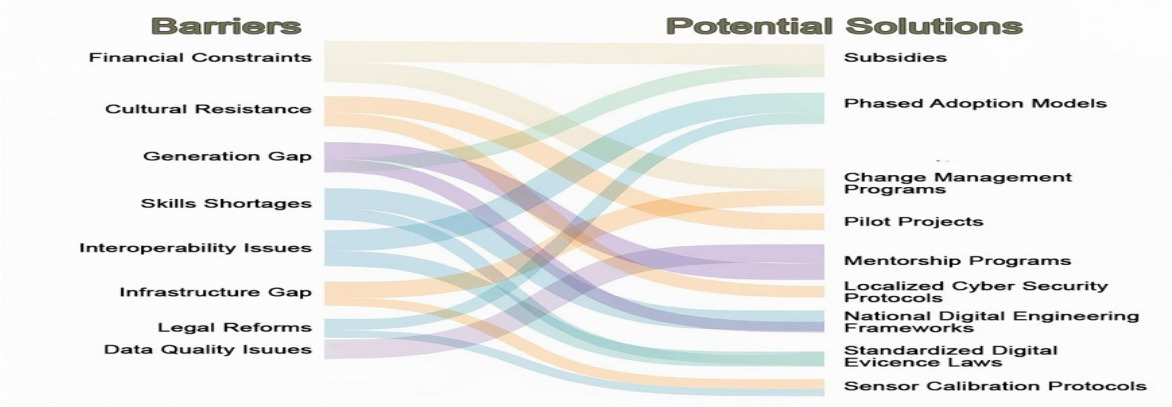

Figure 1: Barrier- Solution Pairing for DTT implementation for CA in Sri Lanka

In these findings, it is further shown that barriers are not static and evolve with changing technological/ contextual shifts. Sri Lanka's problems are unique socio-cultural and regulatory dynamics that compound the problem, global studies focus on skills gaps. Crossing the gap of awareness as a barrier to DTT adoption and introduction of vendor lock in or data quality issues indicate that the mission and purpose of DTT have been clearly understood better, and operators are increasingly advised to adopt a more tailored strategy that considers interaction between financial, technical and human components of DTT adoption.

5. DISCUSSION

This research explains the multivariate barriers to the adoption of Digital Twin Technology (DTT) in the Sri Lankan construction industry, examining technological, economic, organisational, cultural, and regulatory barriers. Major limitations are high financial costs- DTT licences are said to absorb about 20 % of the profit margin of small and medium enterprises (SMEs), skills shortage, and legal reforms. The results also point out the fact that importing global models is constrained by contextual factors including generational gaps and the newly discovered obstacle of vendor lock-in which shows a mature awareness of the complexity of adoption. Besides, these challenges are compounded by local issues, such as cultural legacies, established practices, and infrastructure gaps (especially in rural settings) as well as data-quality risks and systemic policy issues related to data privacy and digital evidence.

Methodologically, the research was a qualitative one using expert interviews (n 10, mainly large organisations/government) which may have under-represented SME and subcontractor views, which are vital in diffusion. Thematic analysis with a top-down approach might have limited emergent themes, and the lack of quantitative data does not allow ranking barriers and modelling interdependencies, which makes generalisation to other emerging economies and highlights the necessity of mixed-methods research in the future.

The empirical evidence indicates that there is a high level of interdependence between the identified barriers and therefore isolated interventions are ineffective. Economic constraints are compounded by technological constraints, e.g. estimated LKR 75 million losses due to data/connectivity problems preventing return on investment, and cybersecurity threats, and infrastructure shortages. The organisational obstacles such as lack of skills and cultural resistance also work in self-reinforcing loops. Since the confidence and feasibility of cybersecurity vulnerabilities and labour shortages have multiplier effects, sequential strategies that are coordinated are more suitable than standalone strategies.

The current study goes beyond the traditional cost-skill dichotomies by putting vendor lock-in into the forefront as a relevant, under-researched constraint in emerging economies. Sri Lankan empirical evidence shows that the use of off-the-shelf platforms by managers increases dependency on Western providers, which hinders local digital transformation (DT). Based on this, the paper critically examines standalone licensing models and finds viable, situational, culturally relevant solutions: hybrid workflows that can narrow the generational gap; phased adoption that can assist SMEs through subsidisation; and open-source platforms that the government can lead to minimise reliance on proprietary systems and promote standardisation. Adoption, in turn, is redefined as the organisation of local sociotechnical ecosystems instead of the complete imitation of Global North patterns. Finally, the paper supports a holistic approach that involves both hybrid workflows and adaptive legal architectures to align local realities with global innovation, which supports sustainable DT in the resource-limited environment in Sri Lanka.

6. CONCLUSIONS

The current research identified 13 context-specific barriers to DTT adoption in the CCA practices of the Sri Lankan construction industry. These barriers were financial, organisational culture resistance, and a severe BIM skilled labour shortage. Several solutions generated by the respondents were suggested to reduce these obstacles including phased adoption models with subsidies, hybrid workflows, and government-led, open-source platforms. Because Sri Lanka is a developing country, the sustainable construction industry of the country presents an opportunity-rich field of CA development through DTT. The current study responds to a topical scientific demand, as no previous empirical research has assessed this integration in the environment of Sri Lanka with its unique socioeconomic and regulatory environment. Future studies ought to aim at empirically supporting the recommendations made and systematically analyse the interdependencies of the related barriers. The research thus equips policymakers with contextual approaches in which they can negotiate adoption complexities. The concept of lack of knowledge in the main construct studies means that there is no previous empirical study on DTT-CA integration in Sri Lanka, and thus there is no direct comparability. In line with this, further studies are justified to empirically support the suggested solutions as well as to investigate interdependencies of the identified barriers.

BARRIERS TO ADOPTION OF AUTOMATION IN INDIAN CONSTRUCTION PROJECTS

Mohammed Akberuddin Adnan[1] and Santhosh Loganathan[2]

ABSTRACT

The construction industry, while a critical economic sector, is characterized by inherent inefficiencies and a relatively low adoption rate of automation technologies. The present research investigates the barriers impeding the adoption of automation in Indian construction projects. A mixed-methods approach was employed, integrating a critical literature review, semi-structured interviews, and questionnaire surveys to investigate the barriers. Initially, a critical review of the existing literature was conducted to identify pertinent barriers. Subsequently, semi-structured interviews with construction professionals were carried out to contextualize these barriers within the Indian construction landscape. The findings from these qualitative phases informed the development of a questionnaire survey, which was pilot-tested and subsequently distributed to construction professionals across India. Statistical methods were utilized to rank the identified barriers. The principal barriers were identified as the need for enhanced training programs, high initial investment costs, and limited stakeholder awareness. Principal Component Analysis (PCA) facilitated the grouping of these barriers into five key components that include industry-related, economic, operational, technical, and human-related barriers. These results underscore the potential of automation to address critical barriers within the construction sector while simultaneously highlighting the necessity of developing targeted strategies to overcome the identified adoption barriers. The present research also offers actionable insights for stakeholders, aimed at promoting the effective adoption of automation and enhancing overall productivity within the Indian construction industry.

Keywords: *Automation Adoption; Automation Barriers; Construction Automation; Indian Construction.*

1. INTRODUCTION

The construction industry significantly contributes to global GDP, yet struggles with persistent issues of productivity, efficiency, and technology adoption. Unlike manufacturing, which has embraced automation, construction remains labour-intensive and fragmented (Bock, 2015). Productivity gains in construction have been negligible compared to manufacturing (McKinsey Global Institute, 2017). Large projects often suffer delays of up to 20% and cost overruns of 80% (McKinsey Global Institute, 2017). Defects account for 10%–25% of construction costs (Get It Right Initiative UK, 2024),

[2] Assistant Professor, Department of Civil Engineering, National Institute of Technology Tiruchirappalli, Tamil Nadu, India, lsanthosh@nitt.edu/santomaills@gmail.com

and the industry saw an 11% increase in workplace fatalities from 2021 to 2022 (US Bureau of Labor Statistics, 2024). These issues underscore the need for innovation through automation. In India, construction remains largely dependent on traditional practices, leading to inefficiencies and delays (Fellows et al., 2012). Fragmentation and a severe shortage of skilled labour exacerbate cost escalations. Though automation can potentially address some of these challenges, its adoption is hindered by multifaceted barriers (Bock, 2015). While countries such as the USA, Japan, China, and Malaysia have made progress, the Indian construction context is relatively slower with regard to adopting automation. Also, there is a paucity of literature on India-specific analysis of automation adoption barriers in construction. To address these gaps, the present study aims to identify and prioritise the barriers to the adoption of automation in Indian construction projects, particularly in the context of large water and effluent treatment projects. By analysing the barriers, the present study seeks to generate insights that can guide policymakers, industry leaders, and technology providers toward effective automation strategies, thereby enhancing safety, quality, productivity, and cost-efficiency in Indian construction projects.

2. LITERATURE REVIEW

Automation in construction refers to technologies that reduce human intervention in executing construction tasks (Groover, 2016). These technologies fundamentally transform conventional methods, including machine-centred approaches, real-time sensing and robotic execution. With Industry 4.0, the scope of automation now includes digitalization and information modelling (Oesterreich & Teuteberg, 2016), supported by CAD-robotics integration and digital fabrication. This study adopts Davis's (2022) definition, encompassing tools and processes that automate construction workflows.

Technologies such as building component manufacturing (BCM) automate off-site fabrication of structural components like floors, walls, and full modules using materials such as steel, concrete, and wood (Bock, 2015). Additive manufacturing (3D printing) is increasingly used for producing customized parts and on-site repairs, although it faces challenges related to material reliability and performance (Delgado et al., 2019). Despite ongoing material development, large-scale component printing is becoming viable. On-site automation includes Single-Task Construction Robots (STCRs) like scaffold-mounted arms, wall-painting robots, and concrete sprayers to perform repetitive tasks (Groover, 2016). However, safety and integration challenges remain, prompting the development of networked robotic factories. Additionally, wearable exoskeletons enhance worker capacity but face barriers of cost, safety, and usability (Chen et al., 2018).

The literature review was conducted using Google Scholar, Scopus, Web of Science, and Science Direct. A total of 114 sources, including 80 journal articles, 20 conference papers, 5 book chapters, and 9 industry reports, were reviewed. This comprehensive review ensured a balanced academic and industry perspective on automation barriers. A systematic approach such as PRISMA was not adopted due to the scoping and exploratory nature of the research, which aimed to broadly map themes and insights across heterogeneous sources rather than evaluate a specific intervention or clinical outcome. The flexibility of the scoping approach allowed for inclusion of diverse publication types and contextual understanding relevant to Indian construction. The literature review revealed that most studies focus on specific automation technologies rather than general barriers, and there is a notable absence of credible research addressing barriers to

automation adoption in Indian construction projects. Table 1 represents the barriers identified from the literature review.

Table 1: Identified barriers

Code	Barriers	Indicative Sources
B1	High initial cost	Tafazzoli et al., (2024), Waqar et al., (2024), Aghimien et al. (2024), Oke et al., (2023), Espinoza et al., (2023), Huang et al. B2	High operation and maintenance cost	Waqar et al., (2024), Aghimien et al., (2024), Oke et al., (2023), Espinoza et al., (2023), Huang et al., (2022), Boya et al., (2022), Kamaruddin et al., (2016), Mahbub (2008)
B3	Easy access to low wage labour	Pradhananga et al., (2021), Delgado et al., (2019)
B4	Lack of government initiatives and support	Aghimien et al., (2024), Oke et al., (2023), Jäkel et al., (2022), Huang et al., (2022), Delgado et al., (2019)
B5	Lack of skilled operator and expertise	Tafazzoli et al., (2024), Liu et al., (2024), Waqar et al., (2024), Aghimien et al., (2024), Oke et al., (2023), Espinoza et al., (2023), Jäkel et al., (2022), Huang et al., (2022), Boya et al., (2022), Bademosi and Issa (2021), Pradhananga et al., (2021), Delgado et al., (2019), Kamaruddin et al., (2016)
B6	Need for training and retraining	Liu et al., (2024), Aghimien et al., (2024), Jäkel et al., (2022), Huang et al., (2022), Bademosi and Issa (2021), Delgado et al., (2019), Mahbub (2008)
B7	Job loss concerns	Tafazzoli et al., (2024), Liu et al., (2024), Oke et al., (2023), Boya et al., (2022), Pradhananga et al., (2021), Bademosi and Issa (2021), Delgado et al., (2019)
B8	Conservative work culture	Liu et al.. (2024), Aghimien et al.. (2024), Huang et al., (2022), Pradhananga et al., (2021), Delgado et al., (2019)
B9	Low level of awareness	Mahbub (2008), Jäkel et al., (2022), Aghimien et al., (2024)
B10	Product complexity	Liu et al., (2024), Aghimien et al., (2024), Oke et al., (2023), Boya et al., (2022), Huang et al., (2022), Pradhananga et al., (2021), Bock (2015), Mahbub (2008)
B11	Immature technology and unproved effectiveness	Aghimien et al., (2024), Liu et al., (2024), Espinoza et al., (2023), Jäkel et al., (2022), Huang et al., (2022), Pradhananga et al., (2021)
B12	Easily and locally not available	Aghimien et al., (2024), Huang et al., (2022), Boya et al., (2022), Kamaruddin et al., (2016), Mahbub (2008)
B13	Fragmented nature of supply chain	Liu et al., (2024), Aghimien et al., (2024), Oke et al., (2023), Huang et al., (2022), Bademosi and Issa (2021), Pradhananga et al., (2021), Delgado et al., (2019), Mahbub (2008)

Code	Barriers	Indicative Sources
B14	Project-based and task-based industry	Liu et al., (2024), Tafazzoli et al., (2024), Espinoza et al., (2023), Jäkel et al., (2022), Huang et al., (2022), Bademosi and Issa (2021), Delgado et al., (2019)
B15	Low level of digitalization	Liu et al., (2024)
B16	Lack of R&D	Liu et al., (2024), Espinoza et al., (2023), Huang et al., (2022), Pradhananga et al., (2021), Delgado et al., (2019), Bock (2015)
B17	Lack of relevant codes and standards	Liu et al., (2024), Waqar et al., (2024), Espinoza et al., (2023), Jäkel et al., (2022), Huang et al., (2022), Bademosi and Issa (2021), Pradhananga et al., (2021)
B18	Safety concerns	Waqar et al., (2024), Tafazzoli et al., (2024), Liu et al., (2024), Aghimien et al., (2024), Espinoza et al., (2023)
B19	Inadequate technical infrastructure	Tafazzoli et al., (2024), Oke et al., (2023), Espinoza et al., (2023), Bademosi and Issa (2021)
B20	Regulations limiting the use	Tafazzoli et al., (2024)
B21	Limited flexibility of automation technologies	Liu et al., (2024), Tafazzoli et al., (2024)

**B1- Barrier Number 1*

3. METHODOLOGY

The present study adopted a mixed-methods approach to examine barriers to automation adoption in Indian construction projects. The methodology integrated qualitative and quantitative techniques to ensure a comprehensive analysis. A critical literature review and semi-structured interviews with industry professionals informed the development of a structured questionnaire, which was pilot tested by 4 experts (3 from industry and 1 from academia). The finalised survey was circulated among construction professionals across India. This triangulated approach combining literature, expert opinion, and field data enabled robust identification of key automation barriers. Such integrative frameworks are recognized as effective for addressing complex AEC challenges, especially where socio-technical resistance exists. Statistical tools were applied to rank and prioritise the barriers, ensuring conclusions were evidence-based and practically relevant. Principal Component Analysis (PCA) was used to group barriers into thematic categories, providing structured and scalable insights.

3.1 DATA COLLECTION

Barriers identified from the literature review guided the design of the initial questionnaire. Semi-structured interviews were conducted with 12 professionals from various sectors of the Indian construction industry (Table 2). These online and offline interviews validated literature findings in the Indian context and identified any additional country-specific barriers. Open-ended questions encouraged respondents to share insights based on their experience. These responses helped refine and expand the questionnaire. A pilot survey

was conducted to check the instrument's clarity and completeness, and feedback led to minor adjustments to improve reliability. The final survey was distributed via Google Forms to 75 professionals with direct or related experience in construction automation, resulting in 66 completed responses. The respondent profile is shown in Table 3. Each barrier was rated on a five-point Likert scale. The survey reached professionals across India, enabling diverse, representative results to support nationally relevant conclusions.

Table 2: Profile in interviewees

Code	Role	Experience	Location (India city)	Duration (min)
P1	P&M Engineer	13	Trichy	26
P2	Site Engineer	10	Trichy	10
P3	Quality Engineer	25	Hyderabad	15
P4	Site Engineer	5	Trichy	10
P5	Contractor	30	Hyderabad	10
P6	Planning Engineer	5	Delhi	20
P7	Project Manager	13	Hyderabad	24
P8	Site Engineer	14	Guwahati	10
P9	Planning Engineer	5	Guwahati	20
P10	Project Manager	28	Hyderabad	15
P11	Automation team	20	Chennai	40
P12	Automation team	8	Chennai	14

**P1-Professional Number 1*

Table 3: Profile of survey respondents

Category	Parameter	Percentage	Category	Parameter	Percentage
Education	Diploma	28.78	Experience	1-5 Years	22.72
	Graduate	43.93		5-10 Years	39.39
	Postgraduate	27.27		10-15 Years	31.81
State	Madhya Pradesh	12.12		15-20 Years	6.06
	Rajasthan	13.63	Department	Execution	27.27
	Karnataka	6.06		Planning	34.84
	Tamil Nadu	25.75		Safety	4.54
	Odisha	42.42		Design	22.72
				Quality	10.6

3.2 DATA ANALYSIS

Statistical techniques were employed to derive meaningful insights. Cronbach's Alpha (α) assessed internal consistency, with values above 0.7 indicating strong reliability (Nunnally & Bernstein, 1994). Shapiro-Wilk and Kolmogorov-Smirnov tests tested data normality (Shapiro & Wilk, 1965), using a p-value > 0.05 as the threshold. Since most

data were non-normal, non-parametric methods were adopted. The Kruskal-Wallis H test evaluated variations across demographic groups (Kruskal & Wallis, 1952). Barriers were ranked using mean and standard deviation, with ties resolved based on lower standard deviations. The dataset's suitability for factor analysis was verified using the KMO test and Bartlett's sphericity test. Principal Component Analysis (PCA) was then applied to reduce dimensionality, extracting factors with eigenvalues above one and using Varimax rotation to enhance interpretability. These components informed the development of strategies to address automation barriers in the Indian construction context.

4. RESULTS AND DISCUSSIONS

The subsequent sections present the findings derived from analysis of the data collected. The identified barriers are ranked and categorized, providing a structured understanding of their relative importance and interrelationships.

4.1 SEMI- STRUCTURED INTERVIEWS

Semi-structured interviews of 12 construction professionals were conducted in offline and online modes to identify the barriers to the adoption of construction automation in the Indian context. The semi-structured interviews gave insights into the barriers based on practical ongoing Indian conditions. The interviews helped in selecting the most critical barriers in the Indian context. Newly identified barriers that were unidentified in the literature and are included in the questionnaire are "need for manual rework (finishes) even after automation" and the "lowest bidder system in awarding contracts". Changes in wordings were made in the survey according to interviews, for instance, identifying barriers from "easy access to labour" to "easy access to low-wage labour", considering the Indian context. The summary of the perceived barriers (as extracts from the interviews), as derived from the semi-structured interviews, is presented in Table 4. A total of 35 barriers to automation adoption were initially identified through literature review, from which 21 barriers were synthesized based on their repetitiveness and their applicability in the Indian context. Two additional barriers derived from interviews were selected for the survey, bringing the total count to 23 barriers. Pilot testing with three industry professionals ensured clarity and design adequacy, leading to finalization of the questionnaire based on their feedback. The main survey was administered using Google Forms, where participants rated each barrier on a five-point Likert scale, and responses were collected widely across Indian construction professionals to ensure robust representation.

Table 4: Summary of semi-structured interviews

Code	Summary (perceived barriers)
P1	Physically active skilled operator required, need for training and retraining, complex to use, high initial, maintenance, operation cost, job security concern, manual work required even after automation, easy availability of low-wage labour, aversion to change, project-based industry, lack of client awareness, complexity of the product.
P2	Need for training, need for skilled operators, high initial, maintenance, and operational costs, lack of government initiatives, lowest bidder system.
P3	Easy availability of low wage labour, low level of awareness, inadequate technical infrastructure supporting implementation, and job security concerns.

Code	Summary (perceived barriers)
P4	Lack of skilled operators and expertise, safety concerns, inadequate technical infrastructure supporting implementation, low level of digitalization, high initial cost, and maintenance costs.
P5	changing site conditions, uniqueness of projects, need for training and retraining, lack of skilled operators, lack of awareness, low project budgets, lack of client support, high initial, maintenance and operation costs, and easily not available.
P6	Lack of R&D, project-based industry, low level of digitalization, poor database management, some projects lack internet connectivity, initial cost, unproven effectiveness, need for training, lack of awareness.
P7	Changing needs for every task, need for training, lack of operators and expertise, low level of awareness/exposure, high initial, maintenance, and operation cost.
P8	High initial cost, easy availability of low wage labour, need for training, lack of skilled operators and expertise, job security concerns.
P9	High initial, maintenance, and operation costs, manual work required even after automation, easy availability of low wage labour, lack of support from top management, need for training, training will not give ROI when workmen are rotated due to sub-contractor, lack of skilled operators and expertise, job security concerns.
P10	High initial cost, inadequate technical infrastructure, job loss for labourers, need for training, lack of skilled operators and expertise, and complex nature of automation technology.
P11	Easy availability of low wage labour, aversion to change, unproven effectiveness, high initial cost, maintenance, low flexibility, need for training, challenging to update, need for training, lack of skilled operators and expertise, lack of codes and standards.
P12	Initial cost, sometimes manual work (finishes) required even after automation, special materials needed (e.g. 3d printing), safety concerns, unproven effectiveness, limited flexibility of automation technologies.

**P1- Professional Number 1*

4.2 RANKING OF BARRIERS

The barriers were ranked according to their Mean Item Score (MIS) and Standard Deviation (SD). Descriptive statistics were done using SPSS software, and Mean Item Score (MIS) and Standard Deviation were calculated. Table 5 represents the final ranking of barriers.

Table 5: Ranking of barriers

Code	Barrier	MIS	SD	Rank
B6	Need for training and re-training	4.015	0.953	1
B1	High initial cost	3.833	1.075	2
B9	Low level of awareness (exposure) among stakeholders	3.712	1.12	3
B5	Lack of skilled operators and expertise	3.697	1.176	4
B12	Easily and locally not available	3.652	1.116	5
B8	Conservative work culture and resistance to change	3.53	1.07	6
B19	Inadequate technical infrastructure supporting implementation	3.485	0.996	7

Code	Barrier	MIS	SD	Rank
B2	High operation and maintenance cost	3.47	1.14	8
B4	Lack of government initiatives and support	3.455	1.01	9
B10	Product complexity	3.455	1.112	10
B23	Lowest bidder system in awarding contracts	3.455	1.139	11
B20	Regulations limiting the use	3.424	0.993	12
B18	Safety concerns	3.364	1.172	13
B11	Immature technology and unproved effectiveness	3.348	1.015	14
B16	Lack of R&D	3.318	1.098	15
B17	Lack of relevant codes and standards	3.318	1.152	16
B7	Job loss concerns	3.303	1.007	17
B14	Project-based and task-based industry	3.303	1.189	18
B21	Need for manual rework (finishes) even after automation	3.303	1.24	19
B3	Easy access to low wage labour	3.288	1.31	20
B22	Limited flexibility of automation technologies	3.273	1.001	21
B15	Low level of digitalization	3.182	1.136	22
B13	Fragmented nature of supply chain	3.121	1.089	23

B1-Barriers Number 1

The barriers with the same MIS value were ranked according to their standard deviation; the factor with the lower standard deviation will be given a higher rank (Delgado et al., 2019), as the lower standard deviation represents a more consistent rating by the respondents to a particular factor.

Reliability analysis yielded a Cronbach's Alpha of 0.925, confirming excellent internal consistency (Nunnally & Bernstein, 1994). Normality tests using Shapiro-Wilk and Kolmogorov-Smirnov methods revealed p-values < 0.05 for all barriers, indicating non-normal distribution (Shapiro & Wilk, 1965), and necessitating the use of the Kruskal-Wallis H-test for further non-parametric analysis (Kruskal & Wallis, 1952). The Kruskal-Wallis H-test showed no statistically significant difference in opinions across different groups of construction professionals, with p-values above 0.05 for all 23 barriers. This indicated a general consensus regarding the barriers affecting automation adoption. For critical ranking, barriers were prioritized based on Mean Item Score (MIS) and Standard Deviation (SD) calculated through SPSS, following methodologies suggested by Olanrewaju et al., (2020). The systematic ranking provided clear insights into the industry's key concerns regarding automation, forming the foundation for subsequent recommendations and strategy development. Need for training and re-training, high initial cost of technologies related to construction automation, low level of awareness (exposure) among construction stakeholders, lack of skilled operators and expertise, and unavailability of automation-related technologies locally and in an accessible manner are top-ranked barriers.

4.3 CATEGORIZATION OF BARRIERS

The categorization of barriers was conducted to condense the number of factors into identifiable subscales using Principal Component Analysis (PCA) (Field, 2013). A minimum of 15 variables is recommended for PCA, which this study satisfied. The Kaiser-Meyer-Olkin (KMO) value achieved was 0.814, which exceeds 0.6 threshold (Kaiser, 1974), while Bartlett's Test of Sphericity produced a significant result ($p < 0.05$) with a chi-square value of 779.616 and 253 degrees of freedom, confirming the dataset's suitability for PCA (Bartlett, 1954). Exploratory Factor Analysis (EFA) using PCA with varimax rotation extracted five principal components explaining a cumulative variance of 62.96%, surpassing the recommended 50% threshold. Two barriers, B8 and B10, were removed for having factor loadings below 0.3 (Field, 2013). The naming of the components was guided by theoretical reasoning and researcher judgment as suggested by Williams et al. (2010), providing a structured categorization of the barriers affecting automation adoption in the Indian construction sector. The categorization derived from this study is presented in Table 6 and discussed below.

Table 6: Categorization of barriers

	Categories	C1	C2	C3	C4	C5
Industry-related barriers						
B12	Easily and locally not available	0.617				
B13	Fragmented nature of supply chain	0.549				
B14	Project-based and task-based industry	0.692				
B16	Lack of R&D	0.524				
B22	Limited flexibility of automation technologies	0.803				
B23	Lowest bidder system in awarding contracts	0.810				
B9	Low level of awareness (exposure) among stakeholders	0.512				
Economic barriers						
B1	High initial cost		0.783			
B2	High operation and maintenance cost		0.684			
B4	Lack of government initiatives and support		0.469			
B6	Need for training and retraining		0.592			
Technical barriers						
B5	Lack of skilled operator and expertise			0.399		
B11	Immature technology and unproved effectiveness			0.338		
B15	Low level of digitalization			0.713		
B19	Inadequate technical infrastructure supporting implementation			0.520		
Operational barriers						
B17	Lack of relevant codes and standards				0.822	
B18	Safety concerns				0.394	
B20	Regulations limiting the use				0.455	

	Categories	C1	C2	C3	C4	C5
B21	Need for manual rework (finishes) even after automation				0.571	
Human-related barriers						
B3	Easy access to low wage labour					0.611
B7	Job loss concerns					0.779
Extraction Method: Principal Component Analysis.						
Rotation Method: Varimax with Kaiser Normalization.						

**C1- Category Number 1*

4.3.1 Industry-Related Barriers

The Indian construction industry encounters several distinct barriers that hinder automation adoption. A major challenge, ranked third, is the "Low level of awareness (exposure) among stakeholders" (B9). Many remain unaware of automation's potential benefits, limiting informed decisions and investment (Jäkel et al., 2022; Mahbub, 2008). Ranked fifth, "Easily and locally not available" (B12) reflects the lack of a domestic supply chain for automation tools, resulting in dependence on costly imports (Boya et al., 2022; Huang et al., 2022). The "Fragmented nature of the supply chain" (B13) adds further complexity, as subcontracting and disjointed workflows make integration difficult (Delgado et al., 2019; Mahbub 2008; Oke et al., 2023). The "Project-based and task-based industry" (B14) also limits ROI on automation, since each project and task is unique—unlike the automotive sector—restricting the reuse of specialized tools (Espinoza et al., 2023; Huang et al., 2022). The "Lack of R&D" (B16) constrains local innovation and adaptation of automation technologies. Similarly, "Limited flexibility of automation technologies" (B21) highlights the inability of current systems to meet diverse construction needs (Liu et al., 2024; Tafazzoli et al., 2024). Finally, the "Lowest bidder system in awarding contracts" (B23) prioritizes short-term cost savings over innovation, discouraging investments in long-term automation solutions.

4.3.2 Economic Barriers

Economic constraints are a major hindrance to automation adoption in India. The top-ranked barrier is the "Need for training and retraining" (B6). This highlights the financial burden of continuously upskilling the workforce to operate and manage advanced systems (Jäkel et al., 2022; Liu et al., 2024). With a predominantly unskilled and semi-skilled labour pool, Indian companies must allocate substantial resources to training, which can discourage automation initiatives. Ranked second, "High initial cost" (B1) of automation technologies remains a primary concern for most stakeholders (Oke et al., 2023; Tafazzoli et al., 2024). Additionally, the eighth-ranked "High operation and maintenance cost" (B2) deters adoption, as many companies lack the financial resilience to bear recurring expenses related to automated equipment (Mahbub, 2008; Oke et al., 2023). "Lack of government initiatives and support" (B4) further exacerbates the problem (Delgado et al., 2019; Oke et al., 2023). Despite India's focus on infrastructure development, policies and subsidies promoting automation adoption remain limited, leaving stakeholders to bear the financial burden entirely. This gap underscores the urgent need for government intervention to incentivize automation adoption through tax benefits, grants, or low-interest loans.

4.3.3 Technical Barriers

The Indian construction sector also grapples with significant technical hurdles. Ranked fourth, "Lack of skilled operators and expertise" (B5) is a major obstacle (Boya et al., 2022). Operating automated machinery and implementing digital systems requires specialized knowledge, which is scarce in India. The seventh-ranked barrier, "Inadequate technical infrastructure supporting implementation" (B19) (Bademosi & Issa, 2021; Oke et al., 2023), further compounds the problem. In many parts of India, such infrastructure is either underdeveloped or entirely absent, making the deployment of automation systems impractical. Another key barrier is the "Immature technology and unproved effectiveness" (B11). Given that automation in construction is still emerging in India, many stakeholders are hesitant to adopt unproven technologies (Aghimien et al., 2024; Espinoza et al., 2023). Moreover, the "Low level of digitalization" (B15) in the construction sector reflects the lack of foundational digital infrastructure required for implementing automation solutions effectively (Liu et al., 2024).

4.3.4 Operational Barriers

Operational barriers also play a significant role in limiting automation adoption. The “Lack of relevant codes and standards” (B17) reflects the regulatory vacuum in India concerning automation in construction. Without clear guidelines and standards, stakeholders are uncertain about the legal and procedural requirements for deploying automated systems (Huang et al., 2022; Pradhananga et al., 2021). "Safety concerns" (B18) remain another critical issue. Despite the potential of automation to improve safety, stakeholders often perceive advanced machinery as risky due to the lack of proven safety protocols and training (Waqar et al., 2024). Similarly, "Regulations limiting the use" (B20) underscore the restrictive policies that hinder the application of automated technologies, particularly in sensitive sectors such as water infrastructure and urban development (Tafazzoli et al., 2024). The "Need for manual rework (finishes) even after automation" (B22) reflects persistent operational inefficiencies, as many automated systems lack the precision needed for certain tasks, requiring manual touch-ups and diminishing automation's overall effectiveness.

4.3.5 Human-Related Barriers

Finally, human-related barriers are deeply rooted in India's socio-economic context. The "Easy access to low-wage labour" (B3) reflects a fundamental barrier to automation adoption (Delgado et al., 2019; Pradhananga et al., 2021). With abundant and inexpensive labour readily available, many contractors see little incentive to invest in costly automation technologies that replace manual work. "Job loss concerns" (B7) further deter automation adoption. The fear of widespread unemployment due to automation is a significant concern in a country with high labour dependency. Stakeholders often prioritize social stability over technological advancement, choosing to maintain traditional practices that ensure job security for unskilled and semi-skilled workers (Delgado et al., 2019; Tafazzoli et al., 2024).

In summary, the barriers identified across industrial, economic, technical, operational, and human dimensions present a comprehensive view of the multifaceted challenges facing automation in Indian construction. Recognizing and addressing these barriers is crucial for developing effective strategies to foster wider technology adoption and drive industry transformation.

5. CONCLUSIONS

The present study critically explored the barriers to the adoption of automation in Indian construction through a mixed-methods approach involving literature review, semi-structured interviews, and a questionnaire survey. A total of 23 distinct barriers were identified and grouped into five core categories: industry-related, economic, technical, operational, and human-related. Among these, the most significant barriers were the need for training and retraining, high initial costs, low stakeholder awareness, and lack of skilled operators. These findings reveal the complex interplay of challenges faced by a traditionally operated industry, where socio-economic diversity and infrastructural limitations continue to impede technological adoption.

The research contributes theoretically by offering a structured, empirically validated framework tailored to India's unique construction landscape. While studies including Delgado et al. (2019) and Mahbub (2008) have assessed global contexts, the present study localizes those findings, accounting for India's infrastructural and policy environment. Practically, it delivers insights regarding construction automation for stakeholders across the sector. Top-ranked barriers, such as high costs and inadequate government support, suggest the need for incentives like subsidies and public-private partnerships. R&D and modular automation can address technical gaps, whereas awareness campaigns can reduce resistance among workers and decision-makers.

The sample, though diverse, may not fully capture regional disparities or micro-level project complexities, representing a limitation. While PCA effectively grouped barriers into themes, it did not examine causal relationships, which future studies could address using SEM or system dynamics. Further research could explore sector-specific automation, cross-country comparisons, and the integration of emerging technologies like AI, BIM-robotics, and digital twins. Overall, a holistic approach addressing technological, economic, operational, and human factors is essential. This study offers a foundation for steering India's construction industry toward a more automated, efficient, and future-ready paradigm.

BEYOND EFFICIENCY: RETHINKING OFF-SITE CONSTRUCTION FOR POST-DISASTER HOUSING RECONSTRUCTION

A.P. Rathnasinghe[1], R.V.A.D. Rahubadda[2], N. Thurairajah[3] and Udayangani Kulatunga[4]

ABSTRACT

The rising frequency and severity of natural hazard-induced disasters has heightened the need for reconstruction strategies that are rapid, yet resilient and responsive to long-term community needs. Off-site construction (OSC) has emerged as an effective approach to post-disaster reconstruction (PDR), offering accelerated delivery, enhanced quality control, and reduced on-site disruption. However, existing research is found to distort OSC's potential by primarily emphasising technical efficiencies while overlooking major barriers such as standardisation issues, cultural insensitivity, and inadequate policy integration. This paper addresses this distortion by conducting a systematic scoping review, supplemented by scientometric analysis. The scientometric review analyses 113 peer-reviewed publications across the years 2004–2025, retrieved from the Scopus database, identifying dominant research themes including modular construction, sustainability, and resilience. Concurrently, the systematic review highlights OSC's key advantages—most notably, time and cost efficiencies—as well as persistent challenges such as high initial investment, logistical constraints, limited policy integration, and insufficient community involvement. Critically, the review suggests that OSC's effectiveness cannot be measured solely by technical efficiency, as the delivery of standardised, culturally disconnected housing may undermine broader recovery goals. For OSC to contribute meaningfully to sustainable reconstruction, it must be integrated within a holistic framework that values local context, supports community agency, and fosters a transition from shelter to home. This study underscores the need for more adaptive, inclusive, and policy-aligned models of OSC in post-disaster settings.

Keywords: *Disaster Resilience; Housing; Off-Site Construction (OSC); Post-Disaster Reconstruction (PDR); Systematic Review.*

1. INTRODUCTION

The global incidence of natural hazard-induced disasters has increased markedly in recent decades, both in frequency and severity (Guha-Sapir et al., 2013). This escalation is

compounded by the persistent rise in global temperatures and sea levels, which continues to pose profound and increasingly unmanageable challenges for many nations (Huang et al., 2018). Even if the most ambitious climate mitigation pledges are fully implemented, they are still projected to be insufficient to stop further global temperature rise (IPCC, 2023). Consequently, extreme weather events are expected to become more frequent and more destructive. These climatic threats are further intensified by rapid population growth and expanding infrastructure, which together have elevated global exposure and vulnerability to natural hazards (Bournay, 2007). As reported by the International Displacement Monitoring Centre, approximately 14 million individuals are displaced annually due to natural disasters (Rashidi & Ghalambordezfooly, 2025).

In response to this growing crisis, governments, policymakers, and humanitarian organisations are increasingly prioritising disaster resilience and preparedness as core policy concerns (Thurairajah et al., 2019). Recognising that no nation is immune to disaster risks, strategic improvements in disaster management—grounded in coordination, foresight, and logistical capability—have become imperative (Guha-Sapir et al., 2013). Within this broader landscape, post-disaster reconstruction (PDR) of houses emerges as one of the most complex yet critical dimensions of recovery (Siriwardhana et al., 2021). Unlike conventional housing projects, PDR of houses must contend with severe time constraints, limited resources, logistical bottlenecks, and the often-fragile socio-environmental contexts of affected areas (Rathnasinghe et al., 2021).

PDR is frequently hindered by chronic delays (Tas et al., 2010), with slow reconstruction prolonging displacement, heightening human suffering, and escalating costs (Weerakoon et al., 2007). On the other hand, financial limitations are acute (Lloyd-Jones, 2006), exacerbated by weak insurance mechanisms and disproportionate emphasis on short-term relief (Ginigaddara et al., 2023). Disrupted supply chains, resource shortages, and labour constraints, further impede progress and compromise construction quality (Rapone et al., 2024). Moreover, fragmented governance, inadequate inter-agency coordination, and top-down planning continue to undermine the effectiveness of reconstruction efforts (Rashidi & Ghalambordezfooly, 2025). At the same time, the pursuit of sustainable and resilient reconstruction—though increasingly recognised as essential—remains constrained by logistical, institutional, and contextual barriers (Rathnasinghe et al., 2024). Conventional construction typically operates within predictable and controlled environments with established timelines, budgets, and logistics, whereas PDR must navigate significant uncertainty, accelerated timelines, resource scarcity, and compromised infrastructure. These unique constraints amplify the relevance and potential of alternative construction techniques in addressing the pressing demands characteristic of disaster recovery contexts (Rathnasinghe et al., 2024).

Amid these challenges, interest in alternative construction strategies has grown, with particular attention to the potential of off-site solutions. Recent efforts have focused on proactive measures such as the deployment of prefabrication and decentralised logistics hubs to support emergency response and reconstruction (Shahzad et al., 2022). Off-site construction (OSC), defined as the manufacturing of prefabricated and non-prefabricated components in controlled factory environments (Rashidi & Ghalambordezfooly, 2025), has gained recognition for its capacity to enhance speed, quality, and efficiency in the built environment. Notably, modular approaches have demonstrated advantages including reduced material waste (MBI, 2010), enhanced quality assurance (Liu et al., 2021), reduced environmental impact (Rathnasinghe et al., 2024), and improved health and safety (MBI, 2010). Other frequently cited benefits include time and cost savings,

decreased dependency on manual labour, and decreased resource depletion (Won et al., 2013). As a premise, OSC represents a promising means for addressing both the speed and quality imperatives of PDR, with potential contributions to more adaptive and resilient recovery systems (Goulding & Rahimian, 2019).

Yet, while OSC has demonstrated clear technical and logistical benefits, its effectiveness in post-disaster contexts cannot be deduced to construction efficiency alone. Research suggests that the provision of standardised, prefabricated dwellings—absent community input, cultural sensitivity, or long-term integration—can undermine the social objectives of reconstruction (Rathnasinghe et al., 2021). Accordingly, a critical appraisal of OSC's potential, limitations, and future pathways when deployed in the PDR of houses is needed. Thus, this study addresses the following research question:

How has Off-Site Construction (OSC) evolved and contributed to post-disaster reconstruction (PDR) of houses, and what are the knowledge gaps, challenges, and future opportunities in its application?

To answer this, the study presents a scientometric and systematic scoping review of 113 peer-reviewed publications from 2004–2025. By synthesising thematic trends, identifying gaps, and evaluating practical implications, this study aims to reposition OSC not as a mere technical fix for PDR of houses, but as a component of a more holistic, inclusive, and policy-aligned reconstruction paradigm.

2. METHODOLOGY

The study adopted a two-phase review methodology integrating scientometric and systematic review techniques. The process involved identifying, screening, and analysing relevant literature, guided by a transparent and replicable methodology.

2.1 LOCATING BIBLIOMETRIC DATA

Scopus was selected as the primary database due to its broader source coverage compared to alternatives such as Web of Science (Rathnasinghe et al., 2024). The search strategy was designed around three interrelated thematic areas: *Off-Site Construction, the Construction Industry, and Post-Disaster Reconstruction*. Specifically, the search utilised comprehensive Boolean logic, systematically combining keywords as follows: ("off-site construction" OR "modular construction" OR "industrialised building systems" OR "prefabricated construction" OR "prefabricated housing" OR "modular building" OR "factory-built housing") AND ("post-disaster" OR "disaster recovery" OR "emergency housing" OR "temporary housing" OR "reconstruction"). The keyword combinations were consistently applied across all database searches to ensure replicability and transparency.

2.2 SELECTION OF THE MOST RELEVANT BIBLIOMETRIC DATA

To ensure methodological rigour, a defined set of inclusion and exclusion criteria was applied during the screening process. These criteria are presented in Table 1.

Table 1: Inclusion and exclusion criteria of research publications

Inclusion Criteria	Exclusion Criteria	Rationale
Publications in English language	Non-English publications	English was adopted for consistency and accessibility in global academic discourse
Publication years 2004–2025	Publications before 2004	The 2004 Indian Ocean tsunami was a turning point in global PDR discourse
OSC and PDR addressed jointly or partially in scope	Studies focusing solely on OSC without disaster context	The study is scoped specifically around OSC's role within post-disaster reconstruction
Peer-reviewed journals or indexed conference proceedings	Non-indexed publications	Ensures academic quality, reliability, and traceability

In determining eligibility, conceptual and theoretical papers were included only if they explicitly provided empirical evidence, rigorous analytical insights, or detailed case-study discussions related to OSC in post-disaster contexts. Purely theoretical or opinion-based articles lacking empirical substantiation or specific practical implications were excluded to maintain analytical rigour. Following this, the selection process adhered to Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines (Moher et al., 2009), as depicted in Figure 1. Using the initial keyword search, a total of 152 studies were retrieved from Scopus databases.

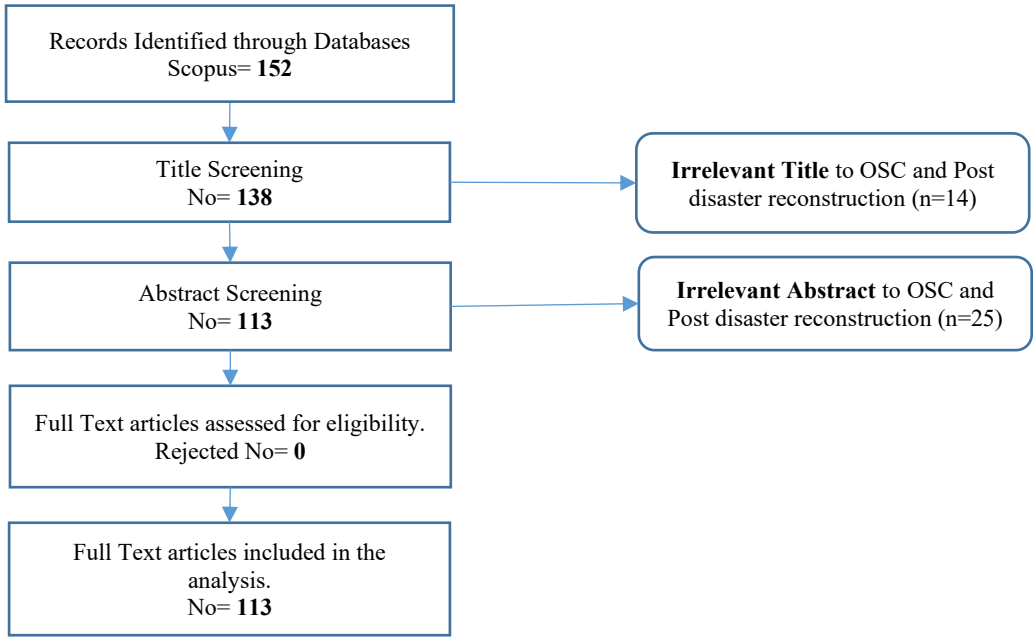

Figure 1: PRISMA guideline for evaluation and screening of retrieved articles from database search

After examining for duplicates and screening abstracts, 39 studies were excluded. The remaining 113 studies met all inclusion criteria and were retained for full-text review and analysis.

2.2.1 Scientometric Review

Rathnasinghe et al. (2024) emphasised scientometric review as an effective mapping tool for visualising connections between keywords, as well as collaborations among researchers, institutions, and countries. In this study, the VOS viewer software was used to generate co-occurrence networks of keywords from the selected 113 publications, allowing the identification of thematic clusters and emerging trends. Overlay visualisation further facilitated the temporal analysis of keyword prominence, revealing how the academic discourse has evolved over the period.

2.2.2 Systematic Review

As part of the review methodology, a systematic review was conducted to delve into the content of the 113 selected publications and assess the depth of knowledge on OSC in PDR. Although scientometric review method effectively maps research networks, it offers limited depth in content interpretation. Therefore, each included article was read in full and critically analysed to extract pertinent information focusing on three core aspects reported in the literature: (1) the advantages/benefits of utilising OSC for post-disaster reconstruction, (2) the challenges or barriers encountered in implementing OSC in such contexts, and (3) the outstanding knowledge gaps or research needs identified.

While the methodological design ensured both breadth and depth, several limitations must be acknowledged. First, the exclusivity of Scopus as the source database may have introduced a degree of publication bias, excluding relevant studies indexed elsewhere or published in non-English languages. Second, the scientometric analysis was purposely scoped to focus on keyword co-occurrence and thematic mapping, excluding dimensions such as author collaboration networks or geographic spread. Finally, although the systematic review aimed to extract and synthesise themes rigorously, it inevitably involved interpretive judgement. Nonetheless, these limitations were mitigated by transparent selection criteria and a reflexive review process, thereby ensuring a robust and credible foundation for the findings presented.

3. FINDINGS OF THE SCIENTOMETRIC REVIEW

This section discusses the scientometric review findings facilitated by VOS Viewer. The trajectory of publications over the studied period and keyword-occurrence are discussed.

3.1 THE ANNUAL PUBLICATION TREND

Figure 2 presents the annual output of research on OSC in PDR, revealing a clear upward trajectory over the past two decades.

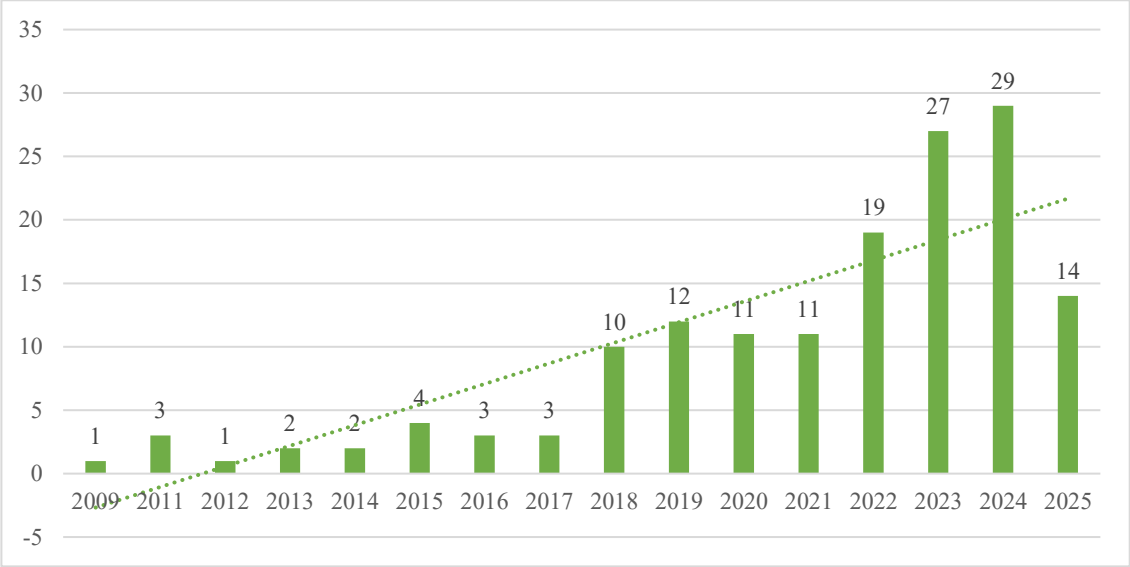

Figure 2: Annual research publications on off-site construction in the context of post disaster reconstruction

From the mid-2000s through the mid-2010s, publication counts remained modest (on the order of 1–4 per year), indicating that OSC in PDR was a niche focus during that period. A pronounced inflection occurs around 2018, after which the volume of publications accelerates markedly – rising to about 10 papers in 2018 and continuing to climb to a peak of 29 in 2024. This steady growth in output suggests that OSC in PDR of houses has moved into the mainstream of scholarly attention. The surge after 2018 likely reflects a confluence of factors: the escalating frequency of climate-induced disasters heightening the urgency for faster reconstruction methods, and technological advances (e.g. modular design, digital fabrication) that made off-site approaches more feasible and appealing. While a slight drop in 2025 (14 publications as of data collection) is observed, this is likely due to incomplete data for that year or a natural stabilisation after the 2024 peak. Overall, the publication trend underscores an increasingly vigorous research focus on OSC within disaster resilience discourse, marking the transition of this topic from a fringe interest to a prominent scholarly domain.

3.2 CO-OCCURRENCE NETWORK OF KEYWORDS

The VOSviewer's keywords co-occurrence mapping (Figures 3–4) offers a holistic view of the scholarly discourse of OSC research in PDR, highlighting which themes have been most prevalent and how the discourse has evolved. From an initial pool of over a thousand distinct keywords across the 113 publications, roughly fifty high-frequency (Freq=3) keywords meet the inclusion threshold of three times frequency to form a network visualisation (refer to Figure 3 (a)).

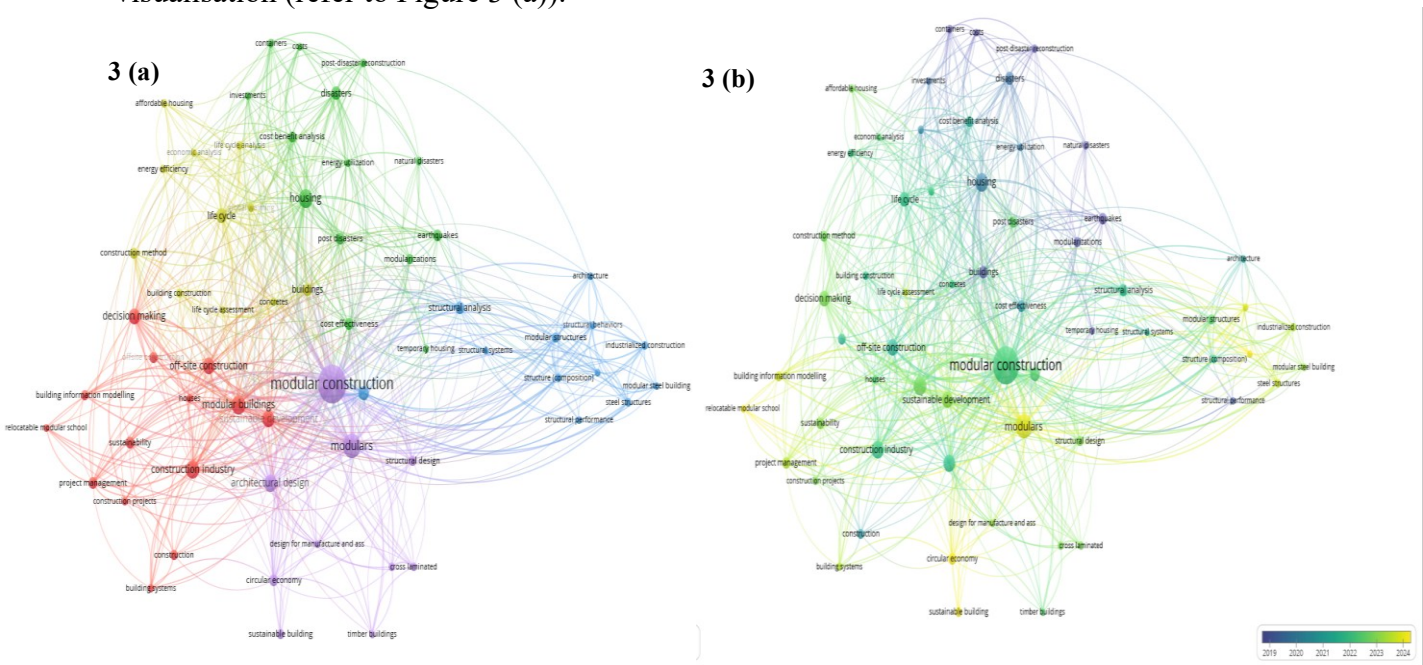

Figure 3: Keywords co-occurrence map for the OSC research in PDR context; (a) network visualisation; (b) overlay visualisation.

Several thematic clusters emerge in this network, each cluster comprising tightly interconnected keywords that denote key research strands. Notably, three overarching themes stand out as focus areas of the literature: *modular construction*, *sustainability*, and *resilience*. The prominence of these clusters suggests that the technical and strategic merits of modular/off-site building methods, as well as considerations of long-term sustainability and hazard resilience, have been focal points driving the OSC-PDR research agenda.

Crucially, the keyword network in Figure 3 informs how tightly OSC research is coupled with the PDR of houses context. The most connected and frequent terms in the network are those directly related to disasters and reconstruction. For instance, keywords such as "*disasters*," "*post-disaster reconstruction*," and similar variations form the core hubs of the map, possessing the highest link strengths (i.e. they co-occur with many other terms). This is evident in Figure 3(b), which shows OSC's robust associations with these disaster-related terms, underlining that nearly all discourse in this field is anchored to the post-disaster context. Figure 4 zooms in on the networks surrounding these pivotal terms: for instance, in the sub-network for "*disasters*" (Figure 4(a)), one observes strong links connecting the disaster theme to practical OSC concepts like "*modular construction*," "*modular buildings*," and "*housing*." Such linkages reveal that a significant portion of research has focused on leveraging modular/off-site building techniques to address the pressing needs of housing reconstruction after disasters. Similarly, the sub-network for "*post-disaster reconstruction*" (Figure 4(c)) is richly connected with OSC-related terms,

reaffirming that off-site construction is increasingly seen as integral to modern reconstruction strategies.

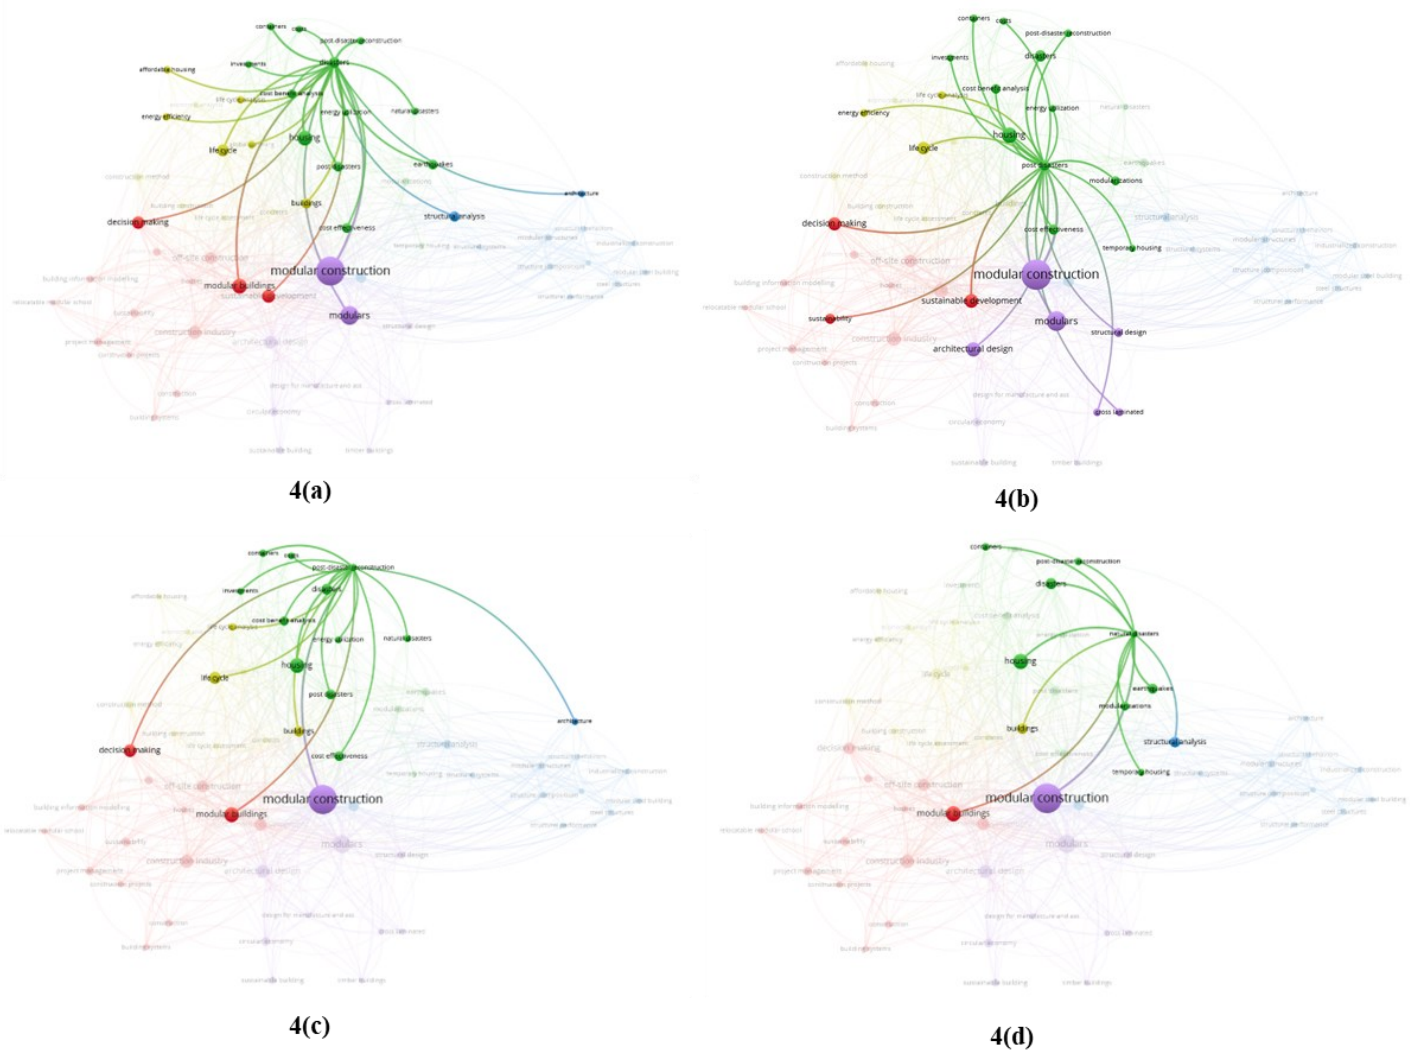

Figure 4: The keywords co-occurrence map of: (a) disasters; (b) post disasters; (c) post disaster reconstruction; (d) natural hazards

The ***evolution of research priorities over time*** is reflected in the changing weight and connectivity of certain keywords. Early in the timeline (mid-2000s), the literature appears to have centred on immediate, logistics-driven concerns – for instance, delivering temporary housing or expediting construction to shelter affected populations. As the field progressed into the 2010s and beyond, the vocabulary of research broadened. Terms related to sustainability and resilience grew more prominent, indicating a shift from purely rapid deployment of OSC towards ensuring that rebuilt communities are safer, greener, and more durable in the long run. This temporal shift, captured by the VOS viewer overlay analysis (Refer to Figure 3(b)), suggests that the academic discourse has matured: recent studies place greater emphasis on the quality and longevity of off-site solutions (e.g., energy-efficient modular units, resilient design for repeat hazards) rather than solely on speed and efficiency. In parallel, we see the emergence of keywords hinting at innovation and integration – for instance, concepts adjacent to OSC like circular economy or building information modelling (BIM) start appearing as the field interfaces

with advancements in construction practice. Such developments point to a research domain that is not only expanding in volume but also deepening in complexity, connecting with broader trends in construction and disaster management.

Another notable pattern in the co-occurrence map is the ***disparity in thematic density between technical and socio-cultural facets of OSC in PDR***. The clusters around engineering and construction-process terms are highly populated and interconnected, reflecting intensive study and a possibly high degree of saturation in those areas. By contrast, keywords that would signify social, community, or policy-oriented aspects (i.e., "community engagement," "policy frameworks," or "governance") are relatively sparse in the network, if present at all. This gap implies that while the engineering and operational benefits of off-site construction have been well documented in the literature, the softer dimensions – such as community acceptance, cultural fit of prefabricated housing, and integration of OSC into policy and institutional arrangements – have not yet received equivalent attention. The current map therefore not only charts what has been extensively studied but also reveals under-explored niches that persist. The lack of dense clusters for these social dimensions highlights an opportunity for future research to balance the discourse, as the field moves toward a more holistic understanding of OSC's role in post-disaster recovery.

4. FINDINGS OF THE SYSTEMATIC REVIEW

While the scientometric analysis offers an overview of thematic structures and publication trends, it does not capture the nuanced content of the existing literature (Rathnasinghe et al., 2024). To address this limitation and enhance the analytical depth, a systematic review was conducted. This review aimed to critically synthesise empirical findings and theoretical insights concerning the use of OSC in PDR of houses. The analysis focused on two central areas: (1) the documented advantages of OSC, and (2) the key challenges or barriers impeding its effective implementation in disaster settings.

4.1 ADVANTAGES OF OFFSITE-CONSTRUCTION IN PDR

The literature reveals a broad consensus on the benefits of OSC, particularly in time-sensitive and resource-constrained post-disaster contexts. As shown in Table 2, these advantages span four main categories: time management, financial efficiency, construction quality, and sustainability.

Table 2: Advantages of using OSC in post disaster reconstruction of houses.

Categories	Advantages	Description	Sources
Time Management	Faster deployment	Enables quick response in emergency reconstruction contexts	[1] [2]
	Time intervals are shorter	Minimises the total project timeline from initiation to completion	[3] [4]
	Parallel construction	Allows simultaneous site preparation and module fabrication	[5] [6]
	Reduced weather delays	Indoor fabrication is less susceptible to adverse weather conditions	[7] [8]

Categories	Advantages	Description	Sources
Financial	Savings on expenses	Lowers long-term project costs through efficiency and standardisation	[1] [2] [3]
	Provide low-cost mass housing	Supports affordable housing scale-up for large, displaced populations	[2] [10]
Quality	Error reduction	Improves precision through factory-controlled processes	[11]
	Enhanced component customisation	Allows design flexibility within modular production constraints	[12] [13]
	Improving productivity and performance	Streamlines construction activities through process optimisation	[9] [14]
Sustainability	Mitigation of environmental impacts	Reduces on-site pollution and supports greener construction practices	[6] [15]
	Enhanced material reuse and recycling	Promotes circular economy through planned material recovery	[4] [15]
	Promotes health and safety	Minimises on-site risk by shifting work to safer factory environments	[9] [13]
	Labour-intensive activities reduction	Reduces reliance on large on-site workforce	[4] [16]

Sources: [1] (Gibb & Isack, 2003) [2] (Aburas, 2011) [3] (Hwang et al., 2018)[4] (Xu et al., 2020) [5] (Wong et al., 2017) [6] (Kamali & Hewage, 2016) [7] (Schuldt et al., 2021) [8] (Lu, 2009) [9] (Abanda et al., 2017) [10] (Pan & Goodier, 2012) [11] (Pan et al., 2012) [12] (Nawari, 2012) [13] (Liu et al., 2021) [14] (Kamali & Hewage, 2016) [15] (Jang et al., 2021) [16] (Razkenari et al., 2020)

One of the most cited and strategically significant advantages is the capacity of OSC to accelerate construction delivery (Aburas, 2011; Gibb & Isack, 2003). In humanitarian settings, reducing time to occupancy is a critical metric of success, particularly where vulnerable populations face prolonged displacement (Shahzad et al., 2022). These expedited timelines are critically beneficial within post-disaster scenarios, directly addressing the urgent need for rapid rehousing to mitigate prolonged displacement and community destabilisation (Rathnasinghe et al., 2021).

Studies such as Rapone et al (2024) have demonstrated the reuse potential of modular units with advanced building envelopes, enabling not only immediate shelter provision but also adaptable responses in repeated disaster cycles. Additionally, OSC's process efficiency translates into tangible environmental benefits through reduced waste, controlled emissions, and safer working conditions—hallmarks of sustainable recovery models.

4.2 CHALLENGES AND LIMITATIONS OF OFF-SITE CONSTRUCTION IN PDR

Despite these strengths, the review also highlights a range of systemic and operational challenges that constrain the broader implementation of OSC in PDR of houses (Refer to Table 3). These are grouped into four overarching categories: technological constraints,

workforce-related barriers, operational inefficiencies, and financial limitations. A critical issue emerging from the literature is the lack of interoperability between OSC systems and local planning or regulatory regimes (Gan et al., 2018; Wuni & Shen, 2020). Without design standardisation, logistics coordination, and clear performance frameworks, the efficiencies promised by OSC are often compromised. This logistical complexity is notably intensified following disasters, as damaged infrastructure, compromised transportation routes, and limited accessibility significantly elevate costs and operational challenges of module delivery and on-site assembly (Gan et al., 2018).

Table 3: Challenges of using OSC in post disaster reconstruction of houses.

Categories	Challenges/ Limitations	Description	Sources
Technological	Damage during transport	Modules may suffer from structural compromise in transit	[1] [2] [3]
	Inferior imports	Low-quality materials or units may undermine long-term durability	[4] [5] [6]
	Rigid for last-minute design modifications	Design changes in post-fabrication are limited or costly	[4] [5] [6]
	Absence of acceptable size and repetition options	Limits adaptability to site-specific needs	[3] [7]
Resource	Early commitment from contractors	Requires upfront planning before full project scope may be clear	[8] [9]
	Inventory control challenges	Difficulty tracking prefabricated units during storage or shipping	[4] [5] [6]
Human	Training for current professionals and courses for new entrances	Demands specialised upskilling in modular systems	[6] [9]
	Lack of competent and professional labour	Shortage of trained workforce hampers quality and speed	[4] [10]
	Inadequate incentives	Lack of policy or financial motivation for industry adoption	[3] [4]
Operational procedures	No standardised design	Fragmented design frameworks delay implementation	[4] [9]
	Lack of standards	Absence of regulatory benchmarks complicates compliance	[2] [3]
	Lack of logistics	Weak transport and storage networks hinder module delivery	[2] [9]
	Intense emphasis on lowest bid price	Cost-cutting undermines quality and innovation	[2] [9]
Financial	High capital expenses	Upfront costs for facilities and technology are substantial	[8] [10]
	Larger initial capital expenditure	Initial funding requirements can discourage uptake	[4] [10]
	Transportation costs	Modules/ panels are costly to move over long distances	[5] [9]

Sources: [1] (Boyd et al., 2013) [2] (Gan et al., 2018)[3] (Hwang et al., 2018) [4] (Lou & Kamar, 2012) [5] (Rahman, 2014) [6] (Aburas, 2011) [7] (Kamali & Hewage, 2016) [8] (Razkenari et al., 2020) [9] (Wuni & Shen, 2020) [10] (Gumusburun & Ay, 2021)

Furthermore, while the technological infrastructure for prefabrication has advanced considerably, the institutional and policy infrastructure to support its widespread application in disaster contexts remains underdeveloped. This results in a fractured implementation landscape, where innovation is often isolated and under-leveraged.

5. DISCUSSION OF FINDINGS

Drawing on both scientometric and systematic reviews, this section reveals the critical trajectories of OSC, with attention to its role in addressing urgent reconstruction needs and its constraints in enabling long-term, socially grounded recovery.

5.1 PERSISTENT GAPS AND STRUCTURAL CONSTRAINTS

Despite clear benefits, the effective deployment of OSC in disaster contexts continues to face substantial implementation and knowledge barriers. In theory, OSC holds transformative potential for disaster recovery—moving beyond simply rapid shelter provision towards sustainable, adaptable housing that can evolve with community needs, supporting both short-term relief and long-term recovery. However, realising this potential remains challenging due to persistent structural constraints. These include bureaucratic delays, inconsistent application of building codes, and a lack of standardised frameworks, all of which significantly diminish OSC's intended advantages of speed and coordination (Rahman, 2014). Operational difficulties related to procurement logistics, transportation, and on-site assembly are particularly under-explored, especially in disrupted infrastructure environments. Social limitations compound these technical issues. A majority of OSC interventions adopt top-down delivery approaches, marginalising local input and often disregarding cultural, spatial, and social contexts (Thurairajah et al., 2019). Consequently, although delivered units might satisfy technical specifications, they frequently fail to support psychosocial recovery effectively. Furthermore, research into the long-term performance and adaptability of modular structures within multi-hazard environments remains limited, casting uncertainty over their sustained resilience (Ginigaddara et al., 2023). Studies exploring the transition of temporary shelters into permanent housing solutions are notably lacking. Few assessments rigorously evaluate life-cycle costs, modular reuse potential, environmental impacts, or post-occupancy performance (Pan & Sidwell, 2011). At the policy level, the transformative potential of OSC remains under-realised. Currently, OSC is often treated merely as a technical fix rather than as a comprehensive and transformative reconstruction approach. Fragmented governance systems and the absence of pre-approved modular standards further restrict its scalability and long-term impact (Zhai et al., 2014).

5.2 INNOVATION PATHWAYS AND RESEARCH FRONTIERS

Recent research trends point toward promising developments that seek to address these limitations. Technologies associated with Industry 4.0—including digital twins, BIM-based DfMA, and AI-driven generative design—are being investigated for their potential to enhance project planning, design flexibility, and resource efficiency (Ginigaddara et al., 2023). Yet, their performance in chaotic, uncertain post-disaster conditions remains largely theoretical, with limited empirical validation to date. Sustainability and circular

construction are also gaining prominence. Modular units embedded with renewable energy systems and reusable components are emerging as conceptual models, though current OSC literature continues to under-represent green design in practice (Abdul & El-adaway, 2020). At the material level, innovations such as seismic-resistant connections and high-performance composites are being trialled to improve the structural integrity of prefabricated buildings. However, these technologies require further testing across varied geographic and hazard contexts to establish their reliability and transferability. Overall, the future of OSC innovation within PDR lies not only in advancing isolated technological or material solutions but also in exploring the interdependencies between physical innovations (materials and modular technologies), information innovations (digital systems and data-driven methods), and cognitive innovations (stakeholder integration, policy alignment, and community-driven design). Therefore, future research should prioritise these integrated pathways, fostering comprehensive frameworks that leverage technological advancements while also emphasising adaptability, contextual sensitivity, and community resilience.

5.3 REPOSITIONING OSC IN THE LONG-TERM RECOVERY CONTINUUM

Of particular significance is a conceptual shift emerging in the literature: a rethinking of OSC housing across its lifecycle. Recent studies increasingly advocate for OSC, particularly modular systems that serve not merely as short-term shelters but as transitional assets capable of evolving into permanent infrastructure (Goulding & Rahimian, 2019). This direction calls for research into modular flexibility, participatory planning, and institutional arrangements that enable OSC to bridge the relief-to-recovery continuum. Taken together, these findings reinforce the view that the value of OSC in PDR cannot be assessed by construction speed or efficiency alone. As the study reveals, rapid deployment often comes at the cost of adaptability and local fit. Without mechanisms to embed OSC within broader recovery strategies, it risks delivering technically competent yet socially disconnected solutions. What emerges instead is the need for a paradigm shift: from viewing OSC as a logistical fix to understanding it as a platform for sustainable, inclusive reconstruction. The construction of housing units must not be conflated with the creation of homes. The latter requires design and delivery processes that are attuned to the lived realities of disaster-affected populations—supporting not only their immediate shelter needs but also their long-term recovery, identity, and community cohesion. This critical reframing of OSC will form the basis for the concluding section, which outlines the policy and research implications of treating OSC not as an end, but to support enduring, culturally responsive, and socially embedded post-disaster housing solutions.

6. CONCLUSION

This study underscores the rising prominence of OSC as a technically capable and logistically agile strategy in PDR. Yet, despite its operational strengths, OSC remains constrained by fragmented policy support, insufficient standardisation, and a persistent disconnect from the social realities of recovery. As it stands, OSC too often delivers structures, not solutions. If OSC is to serve as more than a temporary fix, it must be reframed as a transformative mechanism for recovery—one that not only addresses shelter deficits but actively contributes to rebuilding lives. This requires reimagining the modular unit not as an end-product, but as a platform for social continuity, cultural adequacy, and long-term resilience. In this light, the challenge is not to produce faster

housing, but to co-create '*transformational homes*' that can evolve with the needs and aspirations of displaced communities. Only then can OSC realise its full potential as an enabler of sustainable, dignified, and future-oriented recovery.

BIM IMPLEMENTATION BY INTEGRATING LEAN CONSTRUCTION AND IDT (LCIDT)

Rhijul Sood[1], Nandini Sharma[2] and Boeing Laishram[3]

ABSTRACT

The construction industry, which makes a significant contribution to the country's GDP, continues to grapple with rising costs and project delays. While multiple factors contribute to such overruns one contributing factor is the underutilization or limited deployment of new innovative technologies and procedures. BIM is one such technology/process which have numerous benefits throughout the lifecycle of a project. However, the construction sector is still behind the rate at which innovation should be adopted due to many barriers and a heavy reliance on frameworks based on innovation adoption theories (IDT, TAM, etc.). The study utilized a systematic literature review (SLR) and a document analysis approach to seek answers for the current status of BIM and the hurdles faced by Indian construction stakeholders in its implementation. The shortlisted articles and documents underwent quantitative and qualitative content analysis. The study found that the BIM maturity in India is still very low due to various barriers, which can be eliminated by using a combination of theoretical and practical strategies. Hence, the study proposes a framework ("LCIDT") based on an integrated approach of lean construction (LC) and innovation diffusion theory (IDT) for enhancing BIM implementation. IDT can primarily help in eliminating technical and cost-related barriers, whereas LC can overcome organizational, people, and government-related barriers affecting the utilization of BIM. This framework significantly provides stakeholders with a new perspective on the barriers and integrates theoretical guidance with practical LC applications. However, future research should focus on validating the developed framework across different organizations and geographical locations.

Keywords: *Building Information Modelling (BIM); Innovation Diffusion Theory (IDT); Lean Construction (LC).*

1. INTRODUCTION

The Government of India (GOI) initially allocated ₹111 trillion towards infrastructure development between 2020 and 2025, which further increased substantially to ₹168.93 trillion indicating expanded scope and ambition (Ministry of Finance Government of India, 2020), resulting in huge demand for infrastructure construction as well as maintenance in the country due to the increasing population (Machnoor, 2021). However, as of March 2025, projects worth ₹31.1 trillion have been completed, achieving 28% of the original target. Though pace of construction in the country has tremendously increased with the applications of advanced tools and techniques, however recent studies show that a considerable number of projects overshoot budgets and anticipated timelines (Pal & Nassarudin, 2020; Shendurkar et al., 2022) and encounter difficulties with

cooperation and coordination among the stakeholders throughout the process (Shendkar & Patil, 2017). A significant number of construction projects in India have higher cost-overruns amounting to 63%–141% of the initial budgeted cost and delays up to 79% of preliminary project milestones as compared to the worldwide average (Rajan et al., 2014). As per the June 2024 report by the Ministry of Statistics and Programme Implementation (MoSPI), among a total of 1,817 projects (with a value exceeding INR 150 crores), 458 projects have overshot the initial cost budgets, whereas 831 projects were experiencing time overruns. Some of the most common and important factors for such delays include failure to share relevant project information, lack of collaboration and communication, low productivity of people involved, disagreements among stakeholders, and lack of use of innovative technology, dearth of research on delay factors that are specific to the sector, the impact of delay factors, and the absence of standardization of innovative technologies (PMI and KPMG India, 2019; Saxena et al., 2023).

The increased need for an intelligent and environmentally friendly constructed environment only adds to the complexity of the task (Gupta et al., 2022). Utilization of novel and innovative construction techniques, including digitalization and automation are specific way to enhance the efficiency, value, and administration of construction projects and should be adopted to unleash the industry's enormous potential (Gao et al., 2019). Building Information Modelling (BIM) has been introduced with this objective from the perspective of the construction industry. However, the industry has been slower than other industries in adopting these technologies (Sepasgozar et al., 2019). BIM is widely recognized as a crucial facilitator for effectively identifying risks and achieving the intended construction management objectives among various stakeholders (Aghimien et al., 2022). BIM is revolutionizing the way in which various stakeholders in the construction industry collaborate on projects as a diverse array of BIM software applications is employed during the design, construction, operation & maintenance, and demolition phases (Patel et al., 2021). BIM has been integrated more deeply into various lifecycle phases of construction projects, further facilitating greater digitized industrialization (Gavali & Halder, 2020; Singh et al., 2021) and enhanced project delivery conditions. This has resulted in a notable enhancement in the overall performance of construction projects, from their delivery to management throughout their lifecycle (Raya & Gupta, 2022). Therefore, the Indian construction industry should embrace BIM to reduce project delays and achieve cost-effectiveness in project delivery (Shendurkar et al., 2022).

2. RESEARCH PROBLEM

The adoption of BIM has significantly transformed the processes involved in designing, constructing, delivering, and operating building projects on a global scale. BIM has seen widespread adoption in developed nations, whereas it is rarely put into practice in the context of developing nations (Arokiaprakash & Aparna, 2018). Regarding developing nations, specifically India, it can be observed that the implementation of BIM is still in its initial stages (Ahuja et al., 2020). BIM has been in circulation for a significant duration; however, its level of dissemination is inadequate (Arunkumar et al., 2018), and its application is restricted to visualization (Mohanta & Das, 2022), design management, clash detection, and automatic generation of bill of quantities (BoQs), resulting in low BIM maturity in India (Ahuja et al., 2017; Koul et al., 2023; Sood & Laishram, 2022). Nevertheless, a limited number of studies have endeavoured to leverage BIM tools

beyond traditional applications. These studies have focused on techniques such as integrating linear structures with 3D geometric surfaces to enhance the precision and efficiency of 3D reconstruction in smart city initiatives, thereby streamlining construction and maintenance procedures (Kurup & Bhise, 2024), and a framework to mitigate geometric discrepancies during segmental casting alignment of bridge elements (Babanagar et al., 2023). Additionally, the use of BIM in India is restricted only to urban and large-scale megaprojects, with rare implementation in rural or low-budgeted residential projects (Raya & Gupta, 2022; Surya & Tom, 2022). There have been few studies of BIM implementation in India at different project levels (Bhat et al., 2018; Charlesraj & Dinesh, 2020; Gaur & Tawalare, 2022; Gavali & Ralegaonkar, 2019; Mohanta et al., 2019; Pakhale & Pal, 2020; Rafi & Chari, 2019; Ralegaonkar et al., 2017) and the implementation rate is found to be very low in comparison to other countries owing to various barriers (Dhopte & Daga, 2022; Saxena et al., 2023). Therefore, it can be inferred that even after conducting various studies, BIM implementation among construction firms in India is very low and is attributable to inadequate investigation into the barriers impeding its adoption, as well as the absence of frameworks to address them.

It is recommended that the adoption of BIM in different construction organizations be handled through the lens of innovation (Murphy, 2014). There have been studies across the globe that developed and utilized frameworks based on Innovation Diffusion Theory (IDT) and Technology Acceptance Model (TAM) to understand the process of implementation of such novel and innovative technologies in the construction sector (Fakhimi et al., 2021; Gledson, 2022; Hosseini et al., 2016; Kim et al., 2016). However, even after utilizing such frameworks, the construction sector is still behind the rate at which innovation should be adopted, as these integrations are constrained to the creation of theoretical frameworks that primary stakeholders do not fully comprehend. Therefore, to address the limitations of theoretical models and improve the implementation of BIM through a practical approach, this study attempts to modify the existing frameworks by integrating them with Lean Construction (LC) principles. This approach draws inspiration from the conclusions of a few of the studies that lean construction principles, tools, and techniques can be used to enhance BIM implementation (Barkokebas et al., 2021; Demirdöğen et al., 2021; Mahalingam et al., 2015; Michaud et al., 2019; Piroozfar et al., 2019; Weerasinghe et al., 2023). Few studies that have integrated lean and BIM, with a specific emphasis on BIM as a means to achieve lean goals, have been carried out (Andújar-Montoya et al., 2020; Bhattacharya & Mathur, 2023; Ismail et al., 2023; Moballeghi et al., 2023; Tezel et al., 2020; Uvarova et al., 2023) but these studies lack a holistic framework. Hence, to address these gaps and enhance BIM implementation, the study conducted a systematic literature review to understand the current level of BIM implementation, barriers in its implementation by considering the case of the Indian construction sector and proposed a framework that combines LC and IDT.

3. RESEARCH METHODOLOGY

The research employed a combination of systematic literature review (SLR) and document analysis approach to shortlist academic literature and other documents, respectively, to gain answers to our research problem.

3.1 SYSTEMATIC LITERATURE REVIEW

The systematic review protocol is essential for the identification, screening, and critical assessment of pertinent studies. This procedure also entails the gathering and examining data that will be integrated into a review led by specific research inquiries and explicit methodologies. To organize the literature, the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) method is used (Moher et al., 2009), which involves evidence-based (minimum set) items for conducting systematic reviews and meta-analyses. The aforementioned methodology was instituted in the year 2009 and has gained traction across various research domains in science and technology, owing to its replicability and efficacy in enabling the development of superior processes (Sidani et al., 2021). It involves a four-step process (Shahruddin & Zairul, 2020) and has been adopted by various studies (Charef et al., 2018; Safikhani et al., 2022; Shahruddin & Zairul, 2020; Sidani et al., 2021).

3.1.1 Stage 1: Identification of Database and Keywords

Scopus database served as the primary source of data due to its free accessibility for the authors through their university and is widely recognized as a reputable database engine for academic data. This is because Scopus has indexed a greater number of journals in comparison to other data sources: PubMed, WOS, and Google Scholar (Chadegani et al., 2013). Scopus encompasses a range of data structures, such as keywords, abstracts, article types, authors, journals, institutes, languages, countries, and references, which facilitate the execution of four fundamental search techniques (Khan et al., 2021). Based on our research problem, different keyword blocks such as “BIM”, “barrier”, and “critical success factor”, and their synonyms, the following search syntax was adopted by utilizing Boolean operators "AND" and "OR":

[TITLE-ABS-KEY (“BIM” OR “Building Information Model”) AND (“Barrier” OR “Challenge” OR “Hurdles” OR “Driver” OR “CSF” OR “critical success factor*”)] AND [LIMIT-TO (AFFILCOUNTRY, “India”)].

3.1.2 Stage 2: Screening

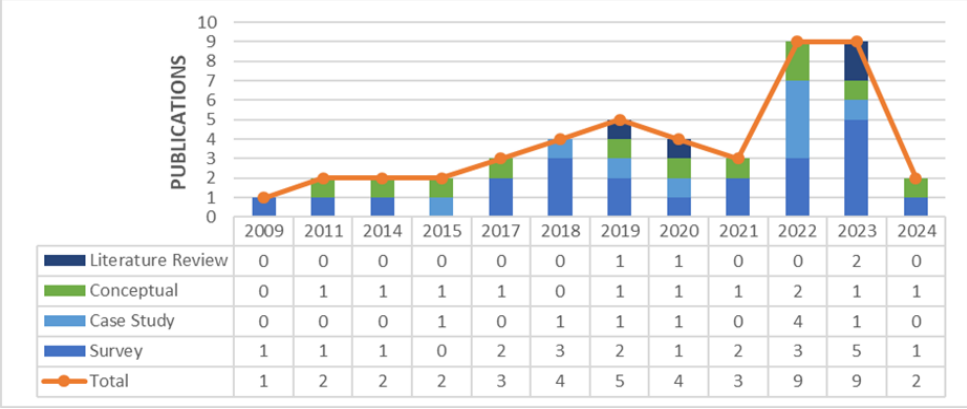
Following the database search, 94 articles were retrieved and were further filtered by language and document type. Only journal and conference articles written in the English language were kept for the next stage, as conference papers serve as a convenient means to enhance an inclusive knowledge of the latest developments in a particular field, thereby facilitating the acquisition of up-to-date knowledge. This step resulted in a list of 78 articles which were downloaded into an MS Excel file.

3.1.3 Stage 3: Eligibility using Inclusion and Exclusion Criteria

The abstracts of the articles from the previous stage were analysed to determine their eligibility based on inclusion and exclusion criteria. The study revealed that a total of 20 articles were sourced from disciplines outside of the construction industry, while 8 articles were deemed irrelevant to the investigation of BIM in India.

3.1.4 Stage 4: Included

During the final stage, an analysis of full-text availability was conducted, revealing that four articles were not present in the database. Therefore, a finalized list of 46 articles was selected to undertake both quantitative and qualitative content analysis.



3.2 DOCUMENT ANALYSIS

Document analysis is a qualitative research methodology that involves the evaluation of many types of documents, including printed and electronic archives (Bowen, 2009). The primary objective of this approach is to generate empirical information and foster a comprehensive understanding of a specific topic. After establishing the study's background and shortlisting academic papers, further analysis was conducted on different documents obtained from online sources (such as blogs, webpages and reports) to enhance the existing knowledge about BIM implementation in India as well as validate the findings of the shortlisted papers (Bagalkotkar & Narain, 2022; Machnoor, 2021; Shetty & Narain, 2021; Verma, 2023).

4. CONTENT ANALYSIS

4.1 QUANTITATIVE ANALYSIS

The quantitative analysis classified the articles based on the year of publication as well as the method of research opted for (Figure 1). The graphical representation illustrates that the emergence of publications about BIM in India commenced in 2009 and has exhibited a favourable upward trend. The year 2009 saw the minimum number of publications, with only one article being published, while the maximum number of publications, with nine articles being published, was observed in the years 2022 and 2023. This indicates a growing interest in BIM-related studies among various researchers in the Indian construction sector. However, the aggregate quantity of BIM-centric scholarly articles published in the years 2020 and 2021 has exhibited a decline in comparison to the corresponding figure for 2019 which could potentially be due to COVID-19 impact. The articles were also classified based on the methods adopted by the authors and are classified into literature review, conceptual, case study, and survey based. The result shows that survey-based methodology that involves online/offline questionnaires, as well as interviews with construction experts, is the most preferred methodology that has been opted for by Indian researchers. Additionally, these 46 selected articles, were also classified based on the type of publications (journal/conference). It was found that 28 articles (61%) were published in various journals whereas the remaining 18 articles (39%) were part of national and international conferences. Among these journal publications, the top 3 journals with a total of 11 articles include Asian Journal of Civil Engineering

Figure 1: Publications based on year and research method

having 5 articles followed by Buildings having 4 articles, and Institution of Civil Engineers with 2 articles.

4.2 QUALITATIVE ANALYSIS

The qualitative analysis helps to conduct the content analysis of the selected articles and other documents. Three different themes/categories for in-depth analysis have been identified.

4.2.1 Geographical Location

A study in Rajasthan (a Northern state of India) modified the BIM based on the needs of rural infrastructure development (Raya & Gupta, 2022). Based on a case study of a rural water management (RWM) project, a rural BIM (R-BIM) model was developed. This model delved into multiple facets, with particular emphasis on the BIM cloud operations, incorporating the active involvement of pertinent stakeholders. In another study conducted in Kerala (a Southern state of India), a methodology that advocates for the integration of Indigenous architectural features into the structural framework was proposed (Surya & Tom, 2022). This approach aims to facilitate the uptake of BIM within the context of residential construction projects. In addition, (Kalidass et al., 2023) conducted a questionnaire survey-based study to investigate the state of occupational safety, health, and environmental standards within the construction sector of Chennai, a major city in southern India. The study aimed to comprehend the existing conditions and assess the integration of BIM for regulatory compliance in these domains. Additionally, various infrastructure projects such as personal rapid transit in Amritsar, Bangalore international airport, Mumbai international airport, Chenab bridge in Kashmir, metro rail in Delhi, and Nagpur have witnessed successful BIM implementation in India (Shetty & Narain, 2021; Verma, 2023).

4.2.2 N-Dimensional BIM

The research on adopting BIM was further refined by incorporating multiple dimensions of BIM into the analysis. In a study conducted in Eastern India, it was determined that BIM was predominantly confined to creating 3D BIM models, primarily due to a variety of technical barriers (Mohanta et al., 2019). Similarly, Charlesraj and Dinesh (2020) surveyed to explore the prevailing level of 4D BIM usage in Indian construction projects. The results revealed that the practical implementation of 4D is very low due to the absence of in-house trained staff, reliance on traditional construction management and contracts, and scarcity of 4D BIM experts. Pakhale and Pal (2020) analyzed the Nagpur Metro Rail Project through a case study approach, with specific attention directed towards assessing both the challenges and benefits entailed in the deployment of a 5D integrated BIM system. The researchers identified the absence of a proficiently trained team, difficulties in converting from 2D drawings to 3D models, and the initial lack of a BIM contract at the project's outset. Similar conclusions have also been drawn by Gaur and Tawalare (2022) from their study of a large-scale project in India that utilized 5-D BIM technology, whereas Sood et al. (2025) emphasizes the importance of sustainability within the construction industry and the potential of 6D BIM for attaining sustainable design for buildings.

4.2.3 Barriers and Action Plans

One of the studies on barriers and action plans influencing Indian construction stakeholders' preference to adopt BIM has investigated the technological, organizational, and environmental factors affecting BIM adoption among different architectural organizations in India (Ahuja et al., 2020). The findings indicate that these firms are currently in the experimentation stage of BIM implementation, primarily due to their inability to identify critical BIM capabilities (Ahuja et al., 2017). Among the most recent studies, Gaur and Tawalare (2022) identified eight primary challenges affecting the implementation of the 5D BIM, Srikanth et al. (2023) identified cultural, legal, financial, lack of skill sets and competence, and management-related factors, whereas Umaapathy & Sundarrajan (2023) did a systematic study based on seven significant factors influencing BIM adoption in India. In another study by Mohanta & Das (2022), an online and interview survey approach was used to rank and find the significance of 14 BIM applications and 12 BIM adoption challenges. Additionally, cost-based factors (such as high costs for software, licenses, hardware, security, staff training, etc.) were found to be major barriers in the majority of studies conducted in India (Arokiaprakash & Aparna, 2018; Gaur & Tawalare, 2023; Sreelakshmi et al., 2017; Verma, 2023). However, a few other significant barriers were related to a lack of collaboration among stakeholders, insufficient resources, limited awareness and knowledge of BIM and ISO 19650 standards, cultural reluctance to adopt new technologies, legal barriers, and dependence on conventional methods (Gaur & Tawalare, 2023; Hire et al., 2021; Machnoor, 2021; Malla et al., 2024; Sawhney, 2014; Singh & Kumar, 2023; Srikanth et al., 2023; Verma, 2023).

Furthermore, a few studies have also suggested various action plans to enhance the adoption and implementation of BIM. To foster broader adoption and implementation of BIM in India, it is imperative to undertake a comprehensive analysis of both the advantages and disadvantages linked to the incorporation of BIM capabilities within organizational frameworks, along with the formulation of ways to overcome the barriers through significant adaptations at both the individual and disciplinary levels (Ahuja et al., 2016). Few studies have suggested that academic measures through BIM education at the university level (Hire et al., 2021), corporate staff training (Patel et al., 2021), organizational support (Umaapathy & Sundarrajan, 2023), social media campaigns (Surya & Tom, 2022), forming BIM groups such as the Indian BIM association (Machnoor, 2021), policy recommendations (Roy & Pawar, 2022), enhanced collaboration and transparent communication between the stakeholders (Gaur & Tawalare, 2022; Singh & Kumar, 2023) can enhance BIM implementation. Moreover, the adoption of BIM in India is often propelled by government mandates, governance models, and standards (Patel et al., 2021; Singh & Kumar, 2023; Verma, 2023), alongside the aspiration of stakeholders to get a tangible return on their investments (Bagalkotkar & Narain, 2022; Charlesraj & Dinesh, 2020; Umaapathy & Sundarrajan, 2023). Few studies have also tried to examine the role of lean construction (LC) principles, tools, and techniques as one of the most suitable strategies for mitigating coordination and collaboration-related challenges, particularly concerning metro projects (Mahalingam et al., 2015) and off-site housing construction in India (Sreeja et al., 2023).

5. CONCEPTUAL FRAMEWORK INTEGRATING LC AND IDT ("LCIDT")

A novel conceptual framework utilizing the "concept mapping" approach has been proposed based on the six-step methodology: preparation, generation of statements, structuring of statements, representation of statements through a concept map, interpretation, and utilization (Kane & Trochim, 2007). This methodology entails the use of visual representations, such as diagrams or pictorial maps, to convey concepts and ideas. The framework incorporates five categories of barriers and demonstrates the role of IDT and LC in eliminating various categories of barriers, as highlighted in Figure 2.

According to academic literature, the diffusion of an innovation approach refers to the transmission of a novel idea disseminated through targeted communication channels within a social system over a defined timeframe, whereas adoption is distinguished by a conscious choice to completely accept an innovation as the best feasible course of action (Rogers, 2003). Innovation Diffusion Theory (IDT) delves into understanding the workings, motivators, and trends of the dissemination of novel ideas and advancements in technology within different societal contexts (Rogers, 2003). The utilization of this concept has been extensive within the realm of Information Technology (IT) research, as it offers valuable perspectives on the uptake, execution, integration, and expansion of IT innovations (Fakhimi et al., 2021). The methodology offers a comprehensive set of quantitative and qualitative instruments to evaluate the probable pace of technology diffusion, while also identifying the factors that either promote or hinder the acceptance and deployment of a given technology. There exist apprehensions regarding the potential assimilation of BIM within the industry, as novel technologies do not invariably yield their anticipated transformative impact and may exhibit a slower-than-expected adoption rate or fail to gain traction altogether (Gledson, 2022). The diffusion of innovation is a phenomenon that is observed throughout society; however, the construction industry experiences a relatively low rate of innovation. As per Rogers (2003), within a given population, the initial 50% of individuals who reach a critical point of innovation adoption are comprised of innovators (2.5%), early adopters (13.5%), and the early majority (34%), while the remaining are composed of the late majority (34%) and laggards (16%). Several scholarly investigations have employed these theoretical frameworks to comprehend the BIM implementation in diverse nations. The utilization of IDT in investigating the BIM adoption among SMEs in Australia (Hosseini et al., 2016), Oil, Gas, and Petrochemical Industry in Iran (Fakhimi et al., 2021), and the UK industry (Gledson, 2022) was observed, whereas, Xu et al. (2014) and Kim et al. (2016) employed an integrated approach that combined the Innovation Diffusion Theory with the Technology Acceptance Model (TAM-IDT), to investigate BIM adoption in China and Korea, respectively.

However, in contrast to the above theoretical perspectives, Lean construction (LC) serves as an overarching term encompassing a blend of operational research and practices customized for the AEC industry, with its origins traced back to the lean production system pioneered by Toyota, a leading Japanese automobile manufacturer (Ballard, 2000; Koskela, 1992; Sacks et al., 2010). The main goal of LC is to eliminate various forms of waste from a process, thereby maximizing the value delivered to the customer (Heigermoser et al., 2019). By leveraging the principles of LC, construction processes can undergo continuous improvement and standardization (Zhang et al., 2016). This suggests that integrating principles from lean concepts can also elevate the maturity level

of BIM within organizations. There have been various studies that consider the use of various lean tools such as the Last Planner System (LPS), Integrated Project Delivery (IPD), Value Stream Mapping (VSM), and the Big Room concept as potential techniques to enhance innovation acceptance across various construction projects (Mahalingam et al., 2015; Michaud et al., 2019; Piroozfar et al., 2019).

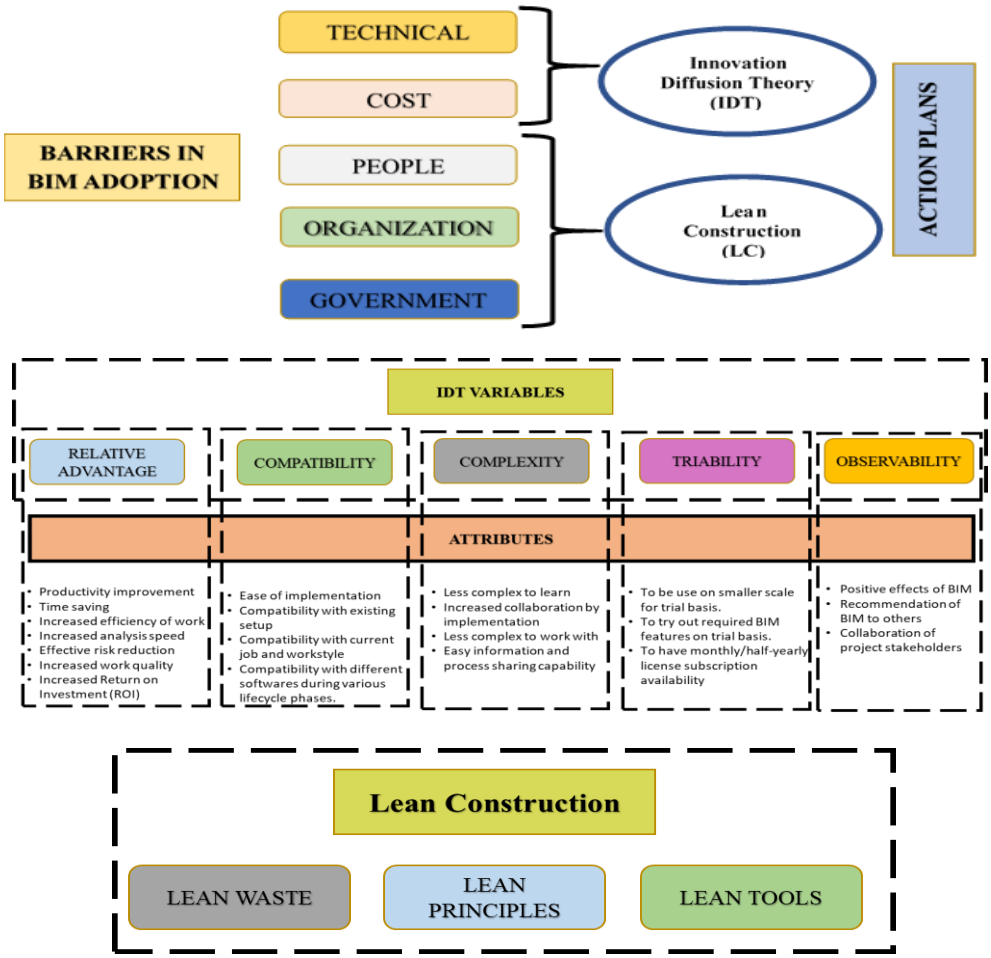

Figure 2: LCIDT - A conceptual framework

Hence, "LCIDT" has been formulated by integrating LC with IDT to demonstrate effective strategies to overcome the barriers. The barriers are classified into five different categories: Technical, People, Organization, Cost, and Government barriers, based on similar other studies (Ahuja et al., 2020; Gaur & Tawalare, 2022, 2023) and demonstrates the role of IDT and LC in eliminating various categories of barriers. As shown in the framework, IDT involves five categories of variables including innovation's relative advantage (perception of the innovation's superiority above current practice), compatibility (extent to which an innovation aligns with prior concepts, and/or perceived necessity.), complexity (level of understanding associated with the utilization or comprehension of an innovation), trialability (the extent to which the innovation can be tried intermittently) and observability (extent to which prospective adopters can perceive the outcomes of an innovation). These five variables include different attributes related to the technical and cost aspects of BIM-related software and can be utilized to select multiple BIM software during various lifecycle phases of a project, depending upon varying levels of necessity. Hence, the IDT variables can be a useful method for

stakeholders to select appropriate BIM software based on their technical requirement and purchasing power, hence eliminating technology (interoperability issues, data privacy/security issues, availability of multiple BIM software, etc.) and cost-related barriers (high cost of software, hardware, risk of low ROI, etc.).

On the other hand, LC cultivates a philosophy of improved coordination and collaboration among different project teams, further establishing a new cultural environment which will consequently amplify the adoption of BIM (Mahalingam et al., 2015). It helps in enhancing organizational learning, which aids companies in value addition through the promotion of innovations (Salehi & Yaghtin, 2015), training and standardization of processes (Schimanski et al., 2021). Furthermore, it improves the early involvement of key participants and increases the level of trust among influential stakeholders (Piroozfar et al., 2019). Additionally, few studies have suggested that enhanced BIM maturity level, as well as integrated BIM implementation (called Level 3 BIM), would not have been achievable without a thorough comprehension and use of LC principles (Barkokebas et al., 2021; Hamdi & Leite, 2012; Koseoglu et al., 2018). Hence, it can be inferred that LC can help in eliminating various organizational (lack of top management support, resistance to change, etc.), people (lack of collaboration, lack of knowledge and BIM training, etc.) and government (lack of standards and mandatory BIM contracts, lack of involvement and initiatives).

6. CONCLUSION

The study developed a framework to enhance the adoption of BIM by integrating the theoretical and practical lenses of IDT and Lean construction, respectively. In this regard, a systematic review of 46 papers (using the PRISMA technique and the SCOPUS database) along with an analysis of various online available documents was done. The authors identified 46 articles that underwent quantitative analysis based on their year of publication, research method employed, and type of article (journal or conference). Based on the qualitative analysis, the studies were analysed based on different geographical locations in India as well as various dimensional applications of BIM. It was found that BIM and other digital technologies have not yet been fully adopted by the Indian construction sector, shedding light on the current status of BIM development as well as the barriers affecting its successful implementation. It was also ascertained from the study that there is a paucity of research on the deep understanding of BIM implementation in India due to various socio-cultural and geographical factors. Furthermore, no prior investigation has employed Innovation Diffusion Theory (IDT) to analyse BIM adoption in the Indian context. Additionally, no framework has depicted the impact of Lean Construction (LC) on improving BIM implementation. Thus, the novelty of this study arises from the development of the framework "LCIDT" by integrating LC with IDT. The IDT can deal with technology and cost-related barriers by comprehending and selecting the necessary BIM tools required for different project trades and applications. Similarly, LC can help to eliminate people, organizations, and government-related barriers through the engagement of lean principles and tools. Utilizing the conceptual framework can help in the pragmatic execution of diverse emerging technologies across different infrastructure domains. Moreover, the framework can be customized according to the specific technology being considered and can be beneficial for implementing different innovations in the AEC Industry. Although the stakeholders are reluctant to deviate from

conventional construction approaches, existing literature strongly supports the implementation of LCIDT in the construction industry for effective technology adoption.

The study focuses on the implementation of LC within project organizations. However, LC applications are presently being utilized by designers, contractors, and consultants, whereas client organizations, which are one of the primary stakeholders for BIM use, remain largely unaware of its potential benefits and implementation. In addition to the contribution of this study to the body of knowledge, as part of future work, the framework can also be further enhanced by categorizing the barriers into distinct lean waste categories, and appropriate lean tools, techniques, and principles can be applied to eliminate them. Additionally, empirical research and surveys can be conducted with different lean implementing organizations and stakeholders to enhance the understanding of the applications of LC for improving the digitalization of the global construction sector. Lastly, the study selected articles from a single database, and to increase the study's comprehensiveness and validity, document analysis from other sources such as webpages, blogs, and reports was also performed. However, the study recommends the use of multiple databases as part of future studies to enhance data reliability.

BRIDGING THE GAP: ENABLING A SECONDARY MATERIAL MARKET FOR CONSTRUCTION AND DEMOLITION WASTE

A.V.R.S. Kavindi[1], I.E. Illeperuma[2] and M.D.T.E. Abeynayake[3]

ABSTRACT

Reintroducing construction and demolition waste (C&DW) to the construction supply chains in the form of secondary materials (SMs) has been in the global limelight over the past decades. However, the underdevelopment/non-existence of SM markets in developing countries stands as a significant barrier. Thus, this study aims to facilitate the widespread reuse of C&DW by reinforcing the SM market in Sri Lanka. The aim was accomplished by conducting an explanatory sequential mixed method research following the survey strategy. Initially, a quantitative questionnaire survey was conducted with 92 respondents, followed by a qualitative survey in the form of semi-structured interviews with 13 experts. Data were analysed through descriptive statistics and content analysis, respectively. Findings revealed that in Sri Lanka, C&DW are directed to landfills on 75% of the occasions, and only 14.47% are directed for reprocessing. Concrete, steel, and timber are the most used C&DW types as SMs. In Sri Lanka, using SMs is limited to post-disaster reconstruction, green buildings, and a few signature projects due to the absence of an established SM market. Therefore, it is crucial to overcome the limited scope and application of SMs and ensure widespread adoption across the CI by establishing a SM market characterised by a web-based digital database. Accordingly, this research contributes the realm of C&DW management, both practically and theoretically by scrutinising the role of the SM market in realising the closed loop and substantiating the ability of the SM market to bridge the gap.

Keywords: *Construction and Demolition Waste (C&DW); Recycling, Repurposing; Reusing; Secondary Material (SM) Market.*

1. INTRODUCTION

The construction industry (CI) constitutes one of the main consumers of raw materials and producers of waste worldwide (Papamichael et al., 2023). Particularly, CI consumes about 50% of the global raw material, accounting for over 35% of the energy-related greenhouse gas emissions and generates about 35% of the world's solid waste (Nawaz et al., 2023). For example, in the European Union (EU), CI is responsible for over 35% of its solid waste (Gherman et al., 2023). The fundamental reason behind the accelerated

construction and demolition waste (C&DW) generation is the reliance upon the linear economic model of "take–make–dispose" (Shooshtarian et al., 2022).

C&DW can be defined as "A resource material that arises from construction, renovation and demolition activities, which needs to be transported from the site and has the potential to be repurposed through downcycling or upcycling" (Caldera et al., 2020, p. 7). It often consists of materials such as concrete, wood, metals, plastics, and bricks, as well as hazardous substances such as asbestos and lead (Bokarde, 2021). Traditionally, C&DW have ended up in landfills, leading to environmental degradation, pollution, inefficient utilisation of lands, unnecessary depletion of natural resources, and habitat destruction (Lindhard et al., 2023). In response, the CI adopted the concept of reverse logistics (RL) to divert C&DW from landfills (Tennakoon et al., 2021). RL supply chain (RLSC) of C&DW is "a chain of activities followed in introducing salvageable material from DW, back to the forward supply chain" (Rogers & Tibben-Lembke, 1998, p 262). It consists of five stages, namely dismantling, sorting and segregation, reprocessing, secondary market operations, and residue disposal (Jayasinghe, Rameezdeen, & Chileshe, 2019). As C&DW passes through the RLSC, recoverable C&DW are converted into value-added resources and introduced to the secondary material (SM) markets, while unrecoverable C&DW are disposed methodically (Tennakoon et al., 2021).

A SM market refers to a structured and often digitalized system that enables the trade, procurement, and reuse of materials recovered from construction, demolition, and restoration activities. These markets serve as intermediaries connecting suppliers of recovered materials with potential users, thereby supporting reverse logistics and promoting circular economy practices in the construction industry (Victar & Waidyasekara, 2023). Using SMs decreases the dependency on virgin materials, minimises carbon emissions from raw material extraction and processing, and generates economic benefits from the C&DW (Bao & Lu, 2020). Despite these benefits, SMs are less popular, especially in developing countries such as Sri Lanka, Bangladesh, and Nigeria, where weak regulatory frameworks, limited awareness, and lack of market infrastructure hinder their widespread adoption (Jin et al., 2019). Importantly, significant gaps exist between waste generation, recovery, and SM markets including the lack of proper waste segregation at source, limited reprocessing capacity, poor integration between waste collectors and reusers, and the absence of centralised platforms to connect recovered materials with potential users (Tennakoon et al., 2021). Having a rapidly expanding CI, growing C&DW generation, and the notable absence of a structured SM market despite increasing interest in circular economy practices exemplifies the need of practicaal and systematic solutions in construction and demolition waste management (C&DWM in the Sri Lanka. In response to this SM market development emerged as a pivotal area of focus in the CI (Shooshtarian et al., 2022). However, there is a lack of research, especially in the Sri Lankan context, that scrutinises the role of the SM market in C&DWM (Victar & Waidyasekara, 2023). Therefore, this study addresses the research question: "How can the gap in C&DWM in Sri Lanka be bridged through the development of a SM market?". The gap refers to the lack of a structured system that enables the recovery, reprocessing, and reuse of C&DW. Thus, the study aims to facilitate the widespread reuse of C&DW by reinforcing the SM market in Sri Lanka. Accordingly, the objectives of the study are: (1) to examine the current practices and challenges in managing the C&DW in Sri Lanka and (2) to explore the industrial need for a SM market in Sri Lanka.

2. LITERATURE REVIEW

2.1 CONSTRUCTION AND DEMOLITION WASTE MANAGEMENT

C&DW can be categorised into two types: inert and non-inert (Caldera et al., 2020). Inert wastes are typically stable, non-hazardous, and suitable for repurposing in construction projects or disposal in public fills (Amararathne & Bandara, 2024). A significant portion of C&DW consists of inert waste, which is further divided into hard and soft inert waste. Hard inert waste includes materials such as rocks and shattered concrete, while soft inert waste includes soil, earth, silt, and slurry (Amararathne & Bandara, 2024). Contrariwise, non-inert waste may biodegrade, burn, or leak dangerous compounds, such as metals, glass, plastics, and wood (Ahmed & Zhang, 2021). Non-inert wastes are usually sent to landfills, considering handling and processing complexities, and negative environmental and health impacts. Therefore, waste segregation is essential for effective reprocessing and mitigating the associated risks (Ahmed & Zhang, 2021). This is further underpinned by the 3Rs: Reduce, Reuse, and Recycle that serve as the basis for C&DWM (Zhang et al., 2022). However, 3R strategy has now been shifted to 10R strategy: *R0-refuse, R1-rethink, R2-reduce, R3 reuse, R4-repair, R5-refurbish, R6-remanufacture, R7-repurpose, R8-recycle, R9-recover, and R10-regenerate* (Gherman et al., 2023).

Regulations have been implemented globally to reduce the negative impacts of C&DW and promote material recovery. For instance, the Waste Framework Directive (2008/98/EC) EU requires 70% of waste from C&DW to be recycled by 2020 (Shooshtarian et al., 2022). The law encourages resource efficiency and extended producer responsibility (EPR) by making stakeholders responsible for the whole lifecycle of materials. Similarly, in Japan, the Construction Engineering Materials Recycling Law mandates that wood, asphalt, and concrete materials be recycled, with the support of government incentives (Zhao, 2021). Although it is not exhaustive for all purposes, the Environment Conservation Act of 1995 in Bangladesh has a fair allowance for waste (Mustofa, 2020). Additionally, the Japanese government offers incentives for companies that utilise recycled materials, promoting a self-sustaining CE within the CI (Purchase et al., 2021). Similarly, in Korea, tightly regulated legislation on C&DWM has led to high reprocessing rates and reduced landfill dependency (Kim, 2021).

C&DW has become a major problem due to rapid urbanisation and accelerated infrastructure development in Sri Lanka (Liyanage et al., 2019). The lack of state mechanisms for collecting, sorting, and processing waste is one of the main obstacles to efficient C&DWM in Sri Lanka (Wijewansha et al., 2021). Though government initiatives encourage sustainability in the CI, they are constrained by inadequate policy enforcement, weak institutional frameworks, and limited stakeholder coordination (Weerakoon et al., 2023). As a result, significant gaps remain in Sri Lanka's approach compared to global best practices. However, the awareness of the economic and ecological benefits of sustainable C&DWM is gradually increasing, driving greater stakeholder involvement in C&DWM (Victar & Waidyasekara, 2023).

2.2 SECONDARY MATERIALS IN CONSTRUCTION

Wood, steel, and concrete are the most common C&DW that can be transformed into SM (Ginga et al., 2020). Reintroduction of waste into supply chains reduces reliance on virgin resources and makes a substantial contribution to resource efficiency (Liyanage et al., 2019). Additionally, permitting SM lessens the reliance on landfills, offers an economical

alternative by lowering the demand for virgin resources, reduces the related extraction expenses, and fosters economic resilience within the construction sector (Haider et al., 2019). Table 1 below depicts the properties of virgin material vs SM.

Table 1: Comparison of virgin material and SM

Property	Virgin Material	Secondary Materials	References
Mechanical Strength	Higher tensile and flexural strength.	Strength decreases with more reprocessing cycles due to polymer degradation. The 20% virgin material combination produced the best mechanical characteristics.	(Rahimi et al., 2014)
Thermal Stability	Higher stability due to intact polymer chains.	Reduced stability with reprocessing cycles; degradation occurs faster, particularly under thermal-oxidative conditions Compared to the virgin polypropylene (451.8 C), the recycled polypropylene had a higher maximum degradation rate temperature (457.1 C).	(Stoian et al., 2019)
Rheological Properties	Lower melt flow index (MFI), indicates higher viscosity and molecular weight.	Higher Melt Flow Index due to polymer chain scission and reduced molecular weight with each reprocessing cycle.	(Rahimi et al., 2014)
Impact Strength	Generally higher and more consistent across conditions.	Impact strength decreases significantly after the first few reprocessing cycles. The impact strength of a material subjected to 20 reprocessing cycles decreased significantly, from 87.7 J/m to 14.2 J/m, yet its functionality remained within a 15% deviation from that of the virgin material.	(Chiu et al., 2018)
Flexibility	Virgin materials maintain better flexibility and strain at break.	Reduced flexibility and elongation at the break due to molecular degradation over cycles.	(Traxler et al., 2023)
Additive Compatibility	Compatible with most standard industrial additives.	Requires higher concentrations of additives (e.g., chain extenders) to restore properties to near-virgin levels. recycled PET requires 15–20% higher additive content compared to virgin PET to achieve near-original tensile strength and thermal stability	(Chiu et al., 2018)

Difficulties in sorting and segregating C&DW due to technological constraints result in inferior quality SMs that might not satisfy industry standards. Additionally, high manufacturing costs related to quality control, advanced reprocessing technologies, and the unpredictable supply of C&DW impact the quality, availability, and price of SMs (Wijewickrama et al., 2021). Ultimately, these constraints lower the market value of SMs

and their ability to compete with virgin alternatives (Wijewickrama et al., 2021), resulting in less demand.

2.3 SECONDARY MATERIAL MARKETS

Establishing a SM market is identified as a sustainable solution to overcome the issues associated with SMs (Shooshtarian et al., 2020). Even though existing SM markets are not operating at the desired level (Jayasinghe, Chileshe & Rameezdeen 2019; Munaro & Tavares, 2023), several noteworthy efforts in establishing SM markets for C&DW can be identified globally. For example, Australia has three SM markets, namely, Buy Recycled, Business Recycling, and ASPIRE (Shooshtarian et al., 2020). Similarly, three SM markets can be identified in the US: 2Good2Waste, Materials Marketplace, and Austin Materials Marketplace. Further, Salza is an SM market operating in Switzerland, while France, Ireland, and India have Backacia, SMILE, and Mjunction, respectively (Shooshtarian et al., 2020).

Those global examples reveal that online platforms, together with digital techniques, thrive as effective SM markets due to their versatility and accessibility (Caldera et al., 2020; Shooshtarian et al., 2020). However, developing a SM market is challenging as it requires careful consideration of various interrelated aspects such as stakeholders' perceptions (Shooshtarian et al., 2020), material procurement, recycling process, plant management and market promotions (Caldera et al., 2020). Once established, SM markets can rapidly grow with the increasing supply of C&DW (Caldera et al., 2020). Moreover, they create numerous direct and indirect employment opportunities, thereby supporting the economy (Nadazdi et al., 2022). However, the absence of a proper SM market is a significant dearth in the Sri Lankan CI, which is mostly attributed to the less regulatory support for C&DW reprocessing (Victar & Waidyasekara, 2023). Therefore, it is essential to study the need for a SM market in Sri Lanka.

3. METHODOLOGY

The study was initiated by carrying out a background study to refine the research area. Next, the objectives of the research were established based on the research question. Research philosophy inspires the way of answering the research question (Saunders et al., 2009). Accordingly, this study adopted pragmatism research philosophy. Consequently, it adopted the ontological assumption that "reality is external and multiple at the same time and that a researcher chooses the view best serves his research purposes" (Saunders et al., 2009) and the epistemological assumption that "both observable phenomena and subjective meanings can provide acceptable knowledge dependent upon the research question" (Saunders et al., 2009). This research employed a mixed-methods approach, combining quantitative and qualitative methods. By conceptualising the ontological, epistemological and axiological stances, Maarouf (2019) concluded that pragmatism is the coherent and integrated paradigm for the mixed research approach. Furthermore, the study employed an 'explanatory sequential mixed methods' design, where the quantitative part was followed by the qualitative part to further explain the quantitative results (Maarouf, 2019).

Under the quantitative part of the study, a questionnaire survey was conducted by distributing the questionnaire via email among 175 construction professionals who were selected through purposive sampling. Accordingly, 92 responses were received, recording a response rate of 52.57%. The purpose of conducting the questionnaire survey

was to gather broad insights from industry practitioners on C&DWM and SM usage in Sri Lanka to identify prevailing trends and key issues. The collected data were analysed using descriptive statistics. Microsoft Excel was utilised for this purpose. Key measures such as weighted arithmetic mean (Equation 1), median, and mode were calculated. Subsequently, a qualitative survey was conducted with 13 experts selected through purposive sampling, as shown in Table 2, to explore the findings in depth and to capture nuanced perspectives on the structural and institutional gaps hindering SM market development in Sri Lanka. The data were collected through semi-structured interviews and analysed using content analysis. NVivo 12 was used in data organisation, coding, retrieval, and data exploration. This study followed the open, axial, and selective coding.

$$\bar{x} = \frac{\int(f \times x)}{\int f} \qquad Equation\ (1)$$

Where f = frequency and x = midpoint of each class.

Table 2: Interviewee profile

Interviewee	Profession	Criteria			
		CQ1	CQ2	AQ1	AQ2
E1	Quality Assurance Manager	√	√	√	
E2	Lecturer	√	√		√
E3	Project Manager	√	√	√	
E4	Project Quantity Surveyor	√	√	√	√
E5	PhD Scholar	√	√		√
E6	Quantity Surveyor	√	√	√	
E7	Engineer, CEO	√	√	√	
E8	Senior Lecturer	√	√		√
E9	Project Manager	√	√	√	
E10	Chartered Architect, Director	√	√	√	
E11	General Manager	√	√	√	
E12	Senior Lecturer	√	√	√	√
E13	PhD researcher	√	√	√	√

Compulsory Qualifications
CQ1 - Degree in construction related fields
CQ2 - Minimum 10 years working experience in construction projects
Additional qualifications (At least one should be fulfilled)
AQ1 - Involvement in Projects which use SMs
AQ2 - Research experience in C&DW management

4. FINDINGS AND ANALYSIS

4.1 METHODS OF MANAGING CONSTRUCTION AND DEMOLITION WASTE IN SRI LANKA

Survey findings revealed the levels of popularity of several C&DWM methods in Sri Lanka, as shown in Table 3.

Table 3: Level of popularity of C&DWM practices

Method	Frequency	Percentage (%)
Incineration	14	15.22
Landfilling	69	75
Let it subcontractor bring out of the project	01	1.08
Maintaining dumping yards	01	1.08
Offsite disposal	02	2.17
Handed over to a licensed waste disposer	01	1.08
On-site segregation of waste	60	65.22
Recycling materials	35	38.04
Reusing materials	38	41.30

Accordingly, landfilling (75%) is the most common method. On-site segregation of waste (65.2%) is also widely practised, indicating the tendency towards sustainable practices by separating reprocess able materials before disposal.

Subsequently, expert interviews explored the current C&DWM practices in depth. The findings showed the emergence of landfilling as the primary method. E2 stated, "*Landfilling is the most used method*," while E6 confirmed, "*the majority went to landfills*." Several respondents, including E5 and E13, emphasised the linear nature of current C&DWM practices. E7 described it as having "*no system in Sri Lanka*," highlighting the absence of organised C&DWM frameworks in many projects.

4.2 CONSTRUCTION AND DEMOLITION WASTE REPROCESSING IN SRI LANKA

Survey respondents were asked to identify the amount of C&DW typically directed for reprocessing from projects that they were involved in Figure 1.

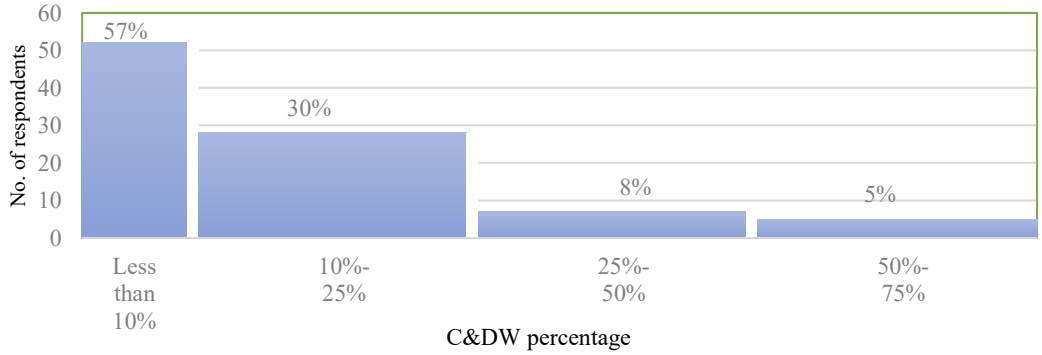

Figure 1 - Percentage of C&DW typically directed for reprocessing

According to Figure 1, occasions where at least one-fourth of the C&DW is directed for reprocessing are 13%. Moreover, as per Equation 1, the weighted arithmetic mean of the quantity of C&DW directed for reprocessing is 14.47%. Thus, despite the tendency towards segregation (as revealed in Section 4.1), only 14.47% of the C&DW is subjected to reprocessing, while the rest is discarded. Furthermore, limited public trust in the

durability of recycled materials and the absence of life-cycle data on SMs restrict their wider acceptance.

Elaborating on this further, the findings of the expert interviews revealed that reprocessing initiatives remain limited in scope and applications. E1 noted, "*it is developing but not up to the required scale*," indicating gradual but insufficient progress. However, E5's observation that recycling was "*rare*" and E6's comment about "*very few recycling approaches*" confirmed that these efforts are not yet mainstream.

4.3 USAGE OF SECONDARY MATERIALS IN SRI LANKA

Figure 2 demonstrates the survey respondents' opinions regarding the importance of using SMs in construction.

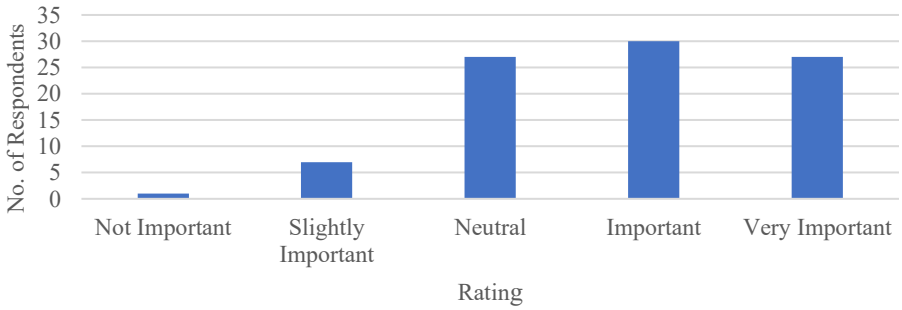

Figure 1: Importance of using SMs in construction

As per the findings, the mode of the data set is 'important', having 32.6% of the responses. Moreover, the 45.5th value holds the median position, which is 'important' as there are 34 responses up to 'neutral' and 64 responses up to 'important'. Accordingly, respondents held a positive attitude towards using SMs in construction. Additionally, 29.34% of the respondents remained neutral. However, despite the positive attitude, C&DW reprocessing is still nascent in Sri Lanka as discussed in section 4.2.

Intending an in-depth exploration of the survey results, the expert interviews focused on the different applications of SMs in the CI. The findings demonstrated varying levels of adoption across different material types. Concrete emerged as the most frequently recycled material, particularly in large-scale projects. E1 and E2 stated, "*in large-scale projects, it is concrete, concrete waste is the most reusable, recycled material*," with applications primarily in road construction as aggregate. E5 explained, "*demolished concrete waste was successfully used for low-volume roads via roller compacted concrete (RCC)*." Steel followed closely, with E12 noting its "*strong resale value*" and "*consistent recovery rates*". Timber reuse was widely reported (E3, E4, E8), though primarily limited to formwork and antique elements (E10). Furthermore, selective recovery of certain construction materials, though at limited scales, was reported. Bricks and roofing tiles showed partial reuse (E1, E7, E11), primarily in small-scale projects, while plastic recycling remained minimal due to technical constraints (E6). Materials such as gypsum are rarely recovered (E12), representing significant untapped potential. As E11 observed, "*we have reduced some of these things, but not for all*," highlighting the inconsistent adoption of material recovery practices across the industry.

Subsequently, the interviewees were questioned about the construction projects which used SMs in Sri Lanka. The responses revealed that while some projects demonstrated

innovation, widespread adoption remains limited. Post-tsunami reconstruction (2004) marked early examples of using SMs. E2 noted, "*in Galle, some projects used SMs after the tsunami*," while E10 added, "*post-tsunami reconstruction incorporated salvaged timber and roofing sheets into new buildings*." These efforts highlight crisis-driven sustainability practices.

Recycling and reusing were emerging, albeit selectively. E3 shared, "*in Kadirana, a converted office block reused 30% of materials, roof tiles and timber for new construction*." Similarly, E7 observed, "*green buildings such as MAS factories and Guga hotel utilised recycled material*s," E8 mentioned, "*a hotel in Dambulla reused C&DW, though I can't recall specifics*." Meanwhile, E9 stated, "*our organization produces paving blocks from plastic and soil-cement blocks for low-rise buildings*." Referring to the Colombo Port City project, E4 reported, "*we reused excavated materials for reclamation*," and E11 elaborated, "*We recycled debris for piling. Our workshop had a dedicated plant*." Additionally, E6 mentioned the Construction Waste Management project funded by the EU (2005–2009) as "*a pilot recycling plant in Galle that processed mixed waste into road aggregates*."

As per the findings, emerging practices reflect shifting norms. Herein, E4 emphasised, "*NSBM Green University mandates waste segregation and sustainability reporting*," while E12 noted, "*some high-rise projects in Colombo pilot on-site recycling, but structured systems are still nascent*." However, E1 admitted, "*I have seen no 100% C&DW reused projects*" and E7 conceded, "*except green-certified buildings, other buildings do not tend to use recycled materials in their projects"*. E11 added, "*recycling is still rare and people do not fully grasp its benefits*." According to E12 Sri Lanka's C&DWM landscape is dotted with '*successful pilots*' but lacks systemic uptake. As E11 summarised, "*using SM at scale is rare*," underscoring the need for policy incentives and industry-wide adoption.

4.4 SM MARKETS IN SRI LANKA

Several interviewees identified market immaturity as the key obstacle. E3 reported, "*people think they [SMs] are degraded and superstitious,"* while E10 observed, "p*eople are not aware of the possibility of using SMs. Herein, e*xperts consistently highlighted the requirement for market development. E13 emphasised that "*we do not have established second-hand market...people always follow clients' requirements for virgin materials.* E7 noted that current usage is "*based on architects' vision, not policy,"* while E9 called for "*a platform"* to facilitate transactions. The accessibility of SMs in Sri Lanka remains limited, with respondents highlighting fragmented supply chains and a lack of formal market infrastructure. E1 noted, "t*here are no very good refinery places,"* while E4 described reliance on informal networks: "*it mostly depends on connections or paper advertisements."* E6 and E12 emphasised the absence of centralised platforms, with E12 stating, "*we do not have a centralised system for trading SMs".* Most transactions occur through small-scale, informal vendors (E7, E9, E11), with E11 observed, "*You cannot buy 100 pieces of door frames".* While few markets exist (e.g., Bellanthota for old doors/windows, E9), broader accessibility is hindered by poor awareness (E10) and a lack of digital databases (E13). Importantly, E5 contended that "*SM markets face accessibility issues."* Without organised hubs or online marketplaces, sourcing remains difficult, particularly for large-scale projects.

The analysis revealed that Sri Lanka's SMs market remains underdeveloped with systemic gaps. While environmental and economic pressures are creating demand (E5, E8, E12), comprehensive solutions addressing market infrastructure and awareness (E4, E9, E10) are needed to accelerate the adoption.

5. DISCUSSION

Agreeing with Caldera et al. (2020), Lindhard et al. (2023), and Shooshtarian et al. (2022) empirical findings of this study confirm that landfilling, which is found to be 75%, is the most common destination of C&DW. On the other hand, the level of on-site segregation, which is discovered as 65.2%, and the positive attitude of the construction professionals towards using SMs, support the claim of Victar & Waidyasekara (2023) regarding the rising efforts and tendency in diverting C&DW from landfilling. Nonetheless, the average reprocessing rate, which is less than 15%, statistically proves the findings of Tennakoon et al. (2021), who highlighted the gaps in C&DW flow between the RLSC stages. Comparatively, in Australia C&DW reprocessing rate is 60%, which is lower compared to other developed countries (Kabirifar et al., 2021). In developing countries such as Bangladesh and Nigeria, weak regulatory enforcement and limited infrastructure hinder effective C&DW reprocessing and the growth of SM markets (Jin et al., 2019).

Additionally, the findings reveal the varying levels of SM usage across different material types. Agreeing with Ginga et al. (2020), concrete was found to be the most common C&DW type, which is used as a SM, followed by steel and timber. Moreover, results reveal that using SMs is not yet mainstreamed in the CI, and the scope is mostly limited to post-disaster reconstruction, green buildings, and a few signature projects. Resonating with the findings of this study, Caldera et al. (2020) highlighted the influence of post-disaster phases. Importantly, findings reveal that most of the signature projects which incorporate SMs have onsite reprocessing facilities or established mechanisms for the reuse of self-generated C&DW. On one hand, this is a noteworthy practice that heading towards a self-sustaining culture. However, on the other hand, SM usage being limited to such projects indicates the immaturity of the SM market.

Thus, this study emphasises the critical requirement of a centralised, established platform which interconnects different RLSC stages of C&DW and thereby ensures the accessibility and timely availability of SMs. Confirming the findings, Victar & Waidyasekara (2023) contended that the absence of an established market discourages potential clients and thereby decreases the demand. Further, the results validate the findings of Caldera et al. (2020), and Shooshtarian et al. (2022) regarding the web-based online SM market and highlight the lack of a digital database for C&DW in Sri Lanka. Material passports, building information modelling (BIM), and Internet of Things (IoT) devices are some commonly practised mechanisms globally to address this issue (Caldera et al., 2020).

Overall, in Sri Lanka, not only is the proportion of C&DW heading to reprocessing aiming to close the loop limited, but also the number of beneficiaries who have the opportunity to enjoy the benefits of SMs is restricted. Findings reveal the reason as the absence of an established SM market, which is backed by a digital database. Therefore, a systemic uptake is essential to outflow the environmental, economic, and social benefits of using SMs in CI beyond the successful pilots.

To the best of the authors' knowledge, this ground-breaking research is the first of that kind which sheds light on a research niche and scrutinises the SM markets in the CI in Sri Lanka. Accordingly, the outcomes of the research greatly contribute to both theoretical and practical bodies of knowledge. Theoretically, this study offers a sound understanding of the role of the SM market in realising the closed loop. Practically, it statistically proves the poor performance of C&DWM in Sri Lanka and establishes the ability to bridge the gap via a SM market.

6. CONCLUSIONS AND RECOMMNEDATIONS

Despite the growing interest towards closing the loop by reintroducing C&DW to the construction supply chains, the effectiveness and efficiency of the entire circular supply chain are affected by the SM market. Thus, this study examines the current status of the C&DW in Sri Lanka and the industrial need for a SM market by following the explanatory sequential mixed method. According to the findings, landfilling is the most common destination of C&DW in Sri Lanka, which is practised on 75% of the occasions. Out of the total C&DW generated, only 14.47% of C&DW is directed for reprocessing. Despite the positive attitude among construction professionals towards SMs, their usage is limited primarily to post-disaster reconstruction, green buildings, and a few signature projects. This is mostly attributed to the absence of a SM market, as the absence limits the accessibility to SMs, thereby resulting in decreased demand for SMs. Accordingly, it is crucial to overcome the limited scope and application of SMs and ensure widespread adoption across the CI by establishing a SM market. Therefore, it is recommended to establish a SM market that is characterised by a web-based digital database for the desired outcomes. Even though this research is conducted in the Sri Lankan context, other developing countries in the region can adopt the findings in their contexts. Further, data collection for the study was limited to construction professionals and industry experts. Thus, future researchers can expand the study focusing on the other stakeholders of the construction supply chains. Further, the next step of the research is to develop a framework for establishing a SM market.

BUILDABILITY MOMENTUM ACROSS PROJECT STAGES: EMPIRICAL INSIGHTS FROM RIBA PLAN OF WORK TOWARDS SUSTAINABLE CONSTRUCTION

P.L.I. Wimalaratne[1] and Udayangani Kulatunga[2]

ABSTRACT

Buildability deals with the optimal integration of construction knowledge at various project stages to achieve the overall project objectives. Incorporation of buildability improves the construction project performance in terms of its cost, quality, productivity, safety, and results in early completion. This study investigates how buildability considerations manifest throughout the RIBA Plan of Work stages, from Strategic Definition-Stage to In Use-Stage7. Using a qualitative methodology, this research draws on semi-structured interviews with a cross-section of industry stakeholders, including designers, contractors, project managers, consultants, and specialists, to uncover how knowledge, stakeholder input, and decision-making practices influence buildability at each stage. Thematic analysis embedded in phenomenological research philosophy was adopted as the data analysis method. The findings show that buildability is often underdeveloped in early design due to limited contractor involvement but becomes more prominent in Spatial Coordination and Technical Design stages through logistics, sequencing, and specialist input. Handover and Use Stages underscore the overlooked importance of commissioning, handover, and facilities management for ensuring project continuity and usability. The study introduces the Buildability Momentum Curve, a visual framework mapping the rising and falling influence of buildability insights across all RIBA stages. This curve underscores the importance of early integration and sustained knowledge flow to mitigate fragmentation and performance inefficiencies. The findings have practical implications for procurement strategies, project governance, and knowledge management systems. By conceptualising buildability as a dynamic and evolving construct, the paper advocates for a more integrated and anticipatory approach to design and delivery that spans the entirety of the project lifecycle.

Keywords: *Buildability; Constructability; Construction; RIBA Plan of Work.*

1. INTRODUCTION

The construction sector plays an essential role in the socio-economic development of a country (Rathnayake et al., 2022). Thus, success in the construction industry is undeniably vital for the growth of a nation (Osuizugbo, 2023). Lack of buildability was identified as a key factor that directly impacts the performance of a construction project

[1] Senior Lecturer, Department of Building Economics, University of Moratuwa, Sri Lanka, indraniw@uom.lk
[2] Professor, Department of Building Economics, University of Moratuwa, Sri Lanka, ukulatunga@uom.lk

(Samimpey & Saghatforoush, 2020). This is because the impact of buildability spans across construction projects, covering the entire procurement process and construction methods (Ansyorie, 2019; Samimpey & Saghatforoush, 2020). Buildability deals with the optimal integration of construction knowledge at various stages to achieve overall project objectives (Wimalaratne et al., 2021). There is a consensus that the design stage is critical for implementing buildability (Naoum & Egbu, 2016). Although some researchers established that buildability measures should be implemented through various stages of construction projects (Aina & Wahab, 2011; Osuizugbo & Oshodi, 2022), some researchers stated that buildability is a project management technique that runs throughout a construction project (Ding et al., 2019; Jadidoleslami et al., 2018; Kifokeris & Xenidis, 2017). Consequently, the existing body of knowledge does not explicitly articulate the presence or continuity of buildability momentum across the various stages of project development. Therefore, this study aims to explore buildability momentum across project stages by drawing on empirical insights from industry practitioners. In this study, "momentum" serves as a metaphor to describe how buildability can accelerate, stagnate, or regress depending on the application of knowledge across project stages. To systematically examine buildability momentum throughout a construction project, the RIBA Plan of Work 2020 was adopted as the structured framework for analysis.

2. LITERATURE REVIEW

2.1 CONCEPTUALISING BUILDABILITY

Buildability has emerged as a direct result of research and practical applications aimed at improving construction projects' efficiency, cost effectiveness, and quality (Griffith & Sidwell, 1997). It is a concept that deals with the optimal integration of construction knowledge and experience at various project stages to achieve the overall project goals (Osuizugbo et al., 2024; Wimalaratne et al., 2023). The Construction Industry Research and Information Association (CIRIA) in United Kingdom (UK) has published the first definition of buildability as, "the extent to which the design of a building facilitates ease of construction, subject to the overall requirements for the completed building" (CIRIA, 1983).

Construction Industry Institute in United States (CII) defined Constructability, a similar term to buildability as, "The optimal use of construction knowledge and experience in planning, design, procurement, and field operations to achieve overall project objectives" (CII, 1986).

Later, the Building Construction Authority in Singapore (BCA) code of practice defined buildability as, "The extent to which the design of a building facilitates ease of construction as well as the extent to which the adoption of construction techniques and processes affects the productivity level of building works" (Building Construction Authority, 2022).

The above definition of buildability varies slightly from territory to territory. Still, the common concept is to foster efficient decision making by fully reflecting construction knowledge and experience throughout the various stages of the project (Lee et al., 2018). Accordingly, the main components of buildability include knowledge sharing, throughout various project delivery phases, and improving construction project performance. As such the key construct of buildability includes knowledge sharing across the stages of a project.

Adding to this, Wimalaratne et al. (2023) identified knowledge sharing as the key driver of the buildability concept.

2.2 KNOWLEDGE SHARING IN CONSTRUCTION

As stated above, 'knowledge sharing' has been identified as the key driver within buildability concept. Knowledge is an exclusive concept. Tsoukas and Vladimirou (2002) described knowledge as, "the individual capability to draw distinctions, within a domain of action, based on an appreciation of context or theory, or both". There are two main types of knowledge: tacit knowledge and explicit/codified knowledge (Nishihara et al., 2017; Nonaka & Konno, 1998; Nonaka & von Krogh, 2009). Explicit/codified knowledge can be expressed in words and numbers and shared through data, scientific formulae, specifications, manuals, and the like (Hoe, 2006). Codified knowledge is generally stored mechanically or technologically in different media (Nonaka, 2007; Nonaka & Konno, 1998) and is readily transmittable between people through manuals and specifications.

Tacit knowledge, on the other hand, is not easily visible. Tacit knowledge is highly personal and hard to formalise, making it difficult to share with others (Hoe & McShane, 2010). Therefore, Tacit knowledge partly consists of hard to pin down technical skills (Nonaka, 2007). Subjective insights, intuitions, and hunches fall into this category of knowledge. Although some research suggests a third type of knowledge as 'implicit knowledge', which is the practical application of explicit, focusing on the two main types of knowledge is relevant in this study.

Knowledge transfer, exchange, or sharing does not have an agreed upon definition, and the terms are often used interchangeably with different connotations, such as information transfer. Nonaka (1994) stated that even though there is a difference, knowledge is formed due to information flows. In construction project delivery teams, knowledge gained through experience can be codified and shared as information; therefore, the terms are interrelated (Garcia & Mollaoglu, 2020). As such, Knowledge sharing involves deeper experiential understanding throughout the construction project delivery process.

2.3 THE CONCEPT OF "BUILDABILITY MOMENTUM"

Many research studies have triggered the emergence of the concepts of buildability carried out around professional fragmentation and poor construction performance in major construction capitals around the world (Wong et al., 2006). In the majority of the studies, there is a consensus that the design stage is critical for implementing buildability (Arditi et al., 2002; Lam & Wong, 2011; Naoum & Egbu, 2016). Adding to that, Low (2011) highlighted that the earlier the considerations towards buildability, the better the potential to influence the outcome. Owing to this, Samimpey and Saghatforoush (2020) emphasised that the presence of a proactive contractor at the pre-construction stage could remarkably enhance the project's buildability. However, the studies conducted by CIRIA, the first to coin the term 'buildability', found that buildability problems widely occur in the construction stages due to a lack of cooperation between designers and planners (Naoum & Egbu, 2015). In addition, CII (1987), in their "Constructability concept file", embraced all stages in building development, which had their respective impacts on achieving the overall project requirements for integrating construction knowledge. Agreeing with CIRIA and CII later studies, many researchers also criticised limiting buildability only to the design stage and argued that improvement measures are to be carried out throughout the whole building process (Griffith & Sidwell, 1997; Samimpey

& Saghatforoush, 2020). For instance, a recent study by Osuizugbo (2020) showed that buildability considerations should start at early project planning and designing stages and continue throughout all construction project stages.

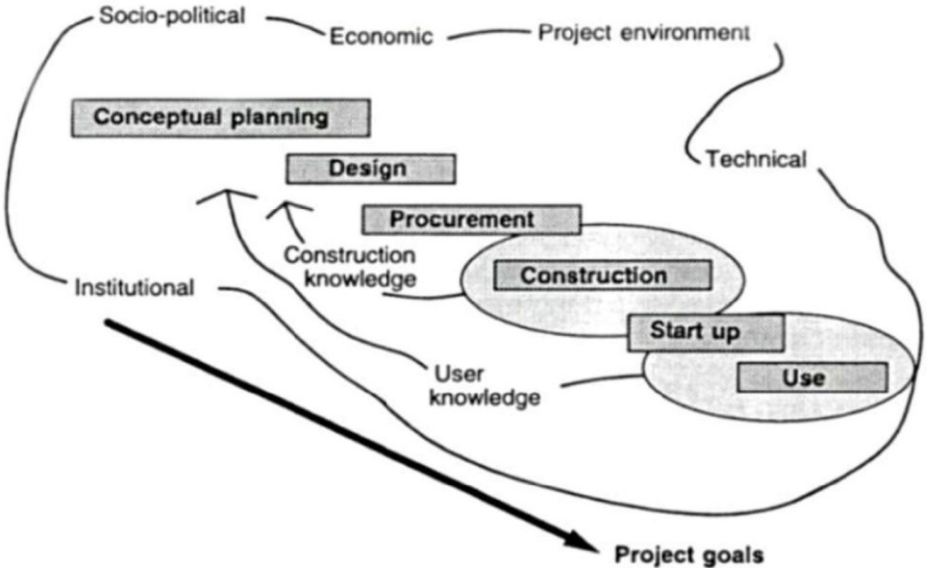

Figure 1: The wider framework of buildability
Source: (CIIA, 1993)

Figure 1 published by CIIA (1993), vividly shows the applicability of buildability in various stages of the construction project.

2.4 USING THE RIBA PLAN OF WORK 2020 AS THE FRAMEWORK

As outlined above, knowledge sharing is essential at every stage of the project delivery process to maximise buildability (Samimpey & Saghatforoush, 2020). Therefore, the selection of a suitable plan of work to capture the stages of the construction project delivery process is necessary. In this regard, several process maps, or plans of work, lay out the generic phases of a construction project. Table 1 below highlights the most prominent examples.

These frameworks and models have been helpful in developing a common language for construction sector activities. Amongst them, the Royal Institute of British Architects (RIBA) developed the most well-known plan of work. The RIBA Plan of Work outlines the activities involved in strategic planning, managing, designing, and administering building construction projects (Haylock, 2021). It organises these activities into several 'work stages'. Therefore, to capture the construction process comprehensively, the RIBA 2020 plan of work is selected as the key process for this study. Further, this plan of work is neutral to all the procurement methods.

Table 1: Comparison of plans of work
Source: (RIBA, 2020)

	Pre-Design		Design				Construction	Handover	In Use	End of Life
RIBA (UK)	0	1	2		3	4	5	6	7	
	Strategic Definition	Preparation and Brief	Concept Design	NOT USED	Developed Design	Technical Design	Construction	Handover & Close Out	In Use	NOT USED
ACE (Europe)	0	1	2.1	2.2	2.3	2.4	3		4	5
	Initiative	Initiation	Concept Design	Preliminary Design	Developed Design	Detailed Design	Construction	NOT USED	Building Use	End of Life
APM (Global)	0	1	2		3	4	5	6	7	
	Strategy	Outcome Definition	Feasibility	NOT USED	Concept Design	Detailed Design	Delivery	Project Close	Benefits Realisation	NOT USED
NATSPEC (Aus)		–	–	–	–	–	–		–	
	NOT USED	Establishment	Concept Design	Schematic Design	Design Development	Contract Documentation	Construction	NOT USED	Facility Management	NOT USED

Accordingly, the construction process development stages for this study are: Stage 0-Strategic Definition, Stage 1-Preparation and Briefing, Stage 2–Concept Design, Stage 3-Spatial Coordination, Stage 4–Technical Design, Stage 5-Manufacturing and Construction, Stage 6–Handover, and Stage 7–Use.

3. RESEARCH METHODOLOGY

Phenomenology is established as the philosophical stance for the study, and abductive reasoning is the research approach (Saunders et al., 2019). Data was collected using phenomenological interview techniques and the analysis was conducted using thematic analysis. Interviews were conducted following a semi-structured guide developed with the findings from the literature. The research strategy for this research is selected as exploratory survey (Saunders et al., 2019). The data analysis process was supported by a computer aided software program called NVivo 14. The study corroborated the findings through internal validation, thus increasing their acceptability. The following Table 2 presents the details of the respondents.

Table 2: Respondents' profile for data collection.

R11	Architect	34
R12	Estimator/Commercial Manager (Post-Contract)-Consultant	17

Professionals with over 15 years of experience with an understanding of buildability were recruited for the data collection through purposive sampling method. Participants were comprised with various stakeholders in the construction industry, such as designers, consultants, contractors, and specialists.

This study has obtained ethical approval from the University of Moratuwa Ethics Review Committee (Ethics Declaration Number: EDN/2022/013).

4. ANALYSIS AND DISCUSSION

This section presents the thematic findings from the qualitative interviews, structured according to the RIBA Plan of Work stages (0–7). Each stage reveals how buildability is understood, operationalised, and challenged throughout the life cycle of a construction project specifically in relation to its key driver, 'knowledge sharing'.

Literature synthesised that buildability discourse focused more on the early stages of construction projects (BCA, 2022; Moore, 1996). According to the research findings, buildability is ongoing throughout the work stages. Supporting this assertion, a recent study by Osuizugbo et al. (2024) introduced a conceptual framework for the execution of 'buildability assessment' during the construction management phase, diverging from the concept's traditional constraint. The literature review did not state a specific type of knowledge applicable to a particular stage of work. However, research findings acknowledged the presence of different knowledge requirements across various work stages of the construction project. Furthermore, literature shows that the stakeholder most responsible or capable of integrating buildability at a specific stage of the construction process varies (Ansyorie, 2019; CIIA, 1993). Agreeing with them, the findings found that the responsibility of buildability shifts among stakeholders throughout the different work stages. The following sub sections summarises the discussion under each work stage.

4.1 STAGE 0 – STRATEGIC DEFINITION

The findings indicated that tacit knowledge dominates at this stage, and early engagement with experienced professionals is critical. R3 stated, "*At the strategic definition stage, very defined, established data driven knowledge has to be there",* while highlighting the people's contribution. It was also noted that limited direct buildability input, but foundational understanding begins at this stage. R1 and R11 were the key contributors to sharing ideas. Key stakeholders involved in this stage include the client, risk managers, financial institutions, environmental consultants, and senior executives.

At this early stage, buildability is primarily framed through strategic foresight, client clarity, and stakeholder alignment. Several participants emphasised the value of engaging experienced consultants to advise clients on defining realistic project scopes and aligning them with future operational expectations. Interviewees highlighted the need to integrate

life cycle thinking from the outset to improve sustainability. Four key themes emerged as: client readiness, early expertise, feasibility thinking, and alignment with user needs.

4.2 STAGE 1 – PREPARATION AND BRIEFING

The respondents confirmed that codified knowledge becomes more relevant at this stage. Cost forecasting and early design estimation were found paramount to improve buildability. R1, R3, R10, R11, and R12 extensively shared their ideas under this theme. Key stakeholders involved include the architect (primary) and other professionals such as commercial managers, structural engineers, clients, project managers, consultants, and environmental experts. Merging the initial stages, R5 stated "So *in Strategic definition stage and preparation and briefing stage obviously clients knowledge and then the QSs and engineers and architects will be using their experience and high level type of knowledge to make decisions*".

At Stage 1, participants stressed the importance of brief robustness, including contributions from contractors and specialists where feasible to ensure sustainable construction outputs. Several interviewees flagged the risks of incomplete briefs, which often lead to later rework and coordination issues. Early contractor involvement (ECI) was advocated, where appropriate, to mitigate these risks and ensure buildability is embedded in early decisions. Key themes that emerged under this stage include early contractor input, stakeholder management, regulatory compliance, and multidisciplinary collaboration.

4.3 STAGE 2 – CONCEPT DESIGN

This stage is the peak point for initiating buildability momentum. Visualisation through modern technologies found enabling problem identification and solution generation. The respondents highlighted the importance of stakeholders' tacit knowledge. The respondents revealed that this stage provides the most conducive platform to convert initial intentions into practical and constructible designs.

The transition from strategic intent to technical resolution of form is where tacit and codified knowledge intersect with increasing complexity. A recurrent sentiment expressed across the respondents (R2, R5, R10, R11, R12) was that buildability concerns must be embedded early within the concept design, with one participant arguing it was "*the best place to integrate buildability or address the buildability issue*" (R10). Another participant elaborated that the integration of practical construction knowledge at this point can facilitate decisions such as the use of climbing scaffolding systems in high rise construction, reducing the need to adapt formwork or methods post design (R2), which influences the buildability of the project.

Interestingly, some respondents (R5, R6, R8) noted the fragmentation of design and construction knowledge, citing that contractor insights are often excluded from Stages 2 to 4. One remarked: "*In separate systems, 2–3 and 4 are completely separated. Contractor's knowledge is not coming in. We should value the knowledge of the contractor*" (R3). This omission presents a barrier to buildability, underscoring the need for procurement methods that foster ECI or frameworks for interdisciplinary knowledge exchange. Another contributor advocated for a knowledge sharing model that bridges expert silos and enables cross disciplinary communication (R6).

This stage highlights a transition from conceptual vision to tangible frameworks that support construction feasibility. Thematic findings show the importance of collaborative environments, particularly with contractor and specialist inputs. Participants noted that decisions regarding structure, materials, and spatial logistics made here are foundational to improving buildability towards sustainable construction delivery. Key themes emerged include specialist engagement, interdisciplinary knowledge exchange, and decision making on material and structural feasibility.

4.4 STAGE 3 – SPATIAL COORDINATION

R3, R4 and R12 extensively shared their view under this theme. Stage 3 of the RIBA Plan of Work represents a critical transition from concept to detailed articulation of the design. In this stage, the implications of design decisions on buildability become more tangible, and the collaborative input of stakeholders intensifies. Input from end-users and technical collaborators at this stage were found vital. Findings from interviews reinforce the imperative of integrating multidisciplinary expertise and recognising the contextual variability of projects, particularly with respect to practical constraints and construction feasibility. According to R2, R7, and R5, tacit and codified knowledge merge during this stage. The interviews revealed a growing emphasis on collaborative detailing through Building Information Modelling (BIM) and other digital platforms. Although not always explicitly mentioned, references to spatial and technical design refinements (e.g., according to R2, "*fine-tune the design*") imply the use of digital coordination tools that synchronise diverse inputs.

At this point, the integration of multiple design disciplines becomes paramount. Interviewees reported that coordination errors and poor technology utilisation at this stage significantly compromise buildability. There was consensus on the need for increased digital maturity and clear interface management across systems. Many participants highlighted the effective use of technologies such as BIM for sustainable construction deliveries. Three key themes emerged include multidisciplinary collaboration and stakeholder engagement, digital collaboration, practical integration of tacit and codified knowledge, and spatial coordination.

4.5 STAGE 4 – TECHNICAL DESIGN

During Stage 4, the translation of conceptual ideas into executable components intensifies. Respondents widely acknowledged this stage as a pivotal zone for integrating practical, codified, and experiential knowledge to ensure that design outcomes are both constructible and aligned with project goals. For instance, R5 highlighted the convergence of scientific rigour and real-world intuition, stating "*detailed calculations based on theoretical stuff*" and the "*need to have your experience and knowledge*" to explain this. This aligns with R4's assertion that this stage requires a blend of "*codified knowledge and tacit understanding*" to ensure that complex technical decisions reflect feasible on-site applications.

Further, R4 underscored the "*technology involvement*" as essential across Stages 3–5, with Stage 4 being particularly dependent on accurate digital detailing to translate the concept into a buildable reality. Hence, buildability at Stage 4 is best understood not as an isolated exercise in technical design but as a cumulative expression of upstream knowledge flows, collaborative engagement, and contextual responsiveness. Both R5 and

R7 agreed that codified knowledge leads in this stage, while tacit knowledge guides critical judgements.

Participants identified this stage as a critical buildability inflexion point. Key concerns included insufficient buildability reviews, unclear detailing, and the marginalisation of construction knowledge. Several interviewees advocated for structured reviews, involving both contractors and trade specialists, to test the buildability of drawings before final sign-off. Three key themes emerged under this stage, including convergence of practicality and precision, stakeholder expansion and technical interdependence, and interdisciplinary detailing and digital collaboration.

4.6 STAGE 5 – MANUFACTURING AND CONSTRUCTION

The findings from Stage 5 present a pivotal shift in the nature and dominance of knowledge contributions to buildability. Unlike the early design stages, which were heavily conceptual and reliant on collaborative insight, this stage embodies the tangible execution of design intent, where tacit knowledge and real time problem solving are paramount.

A consistent theme across multiple respondents' responses is the recognition of the 'contractor's central role' in shaping buildability during this stage. Contractor led knowledge, described as both superior and practical, was repeatedly highlighted as essential for effective execution. For instance, R9 asserted that "*contractor's know how is more prominent*" proposing that their practical grasp often outweighs that of design professionals when it comes to complicated construction challenges. This sentiment is echoed by R10, who emphasised the value of the "*project manager's integrative knowledge*" and the "*critical importance of logistics and construction sequencing*", both of which directly influence the buildability of construction on site.

Another emerging theme was the "dual reliance on tacit and codified knowledge". While some participants (e.g., R5, R12) stressed the enduring importance of building codes, standard documents, and theoretical frameworks, there was a clear consensus that "practical, experiential understanding" accumulated over time and contextualised to site-specific conditions becomes dominant at this stage. The interviews revealed that presence of external stakeholders such as regulatory bodies, utility providers, financial institutions, and safety officers adds another layer of complexity to buildability. These contributors not only verify compliance but also influence temporal and logistical dimensions, reinforcing the need for early coordination and robust communication pathways established throughout RIBA stages.

R4 emphasised that "knowledge pooling" and collaborative discussions at this stage are essential for a coherent execution strategy. Meanwhile, R1 and R10 outlined the necessity for "multi-disciplinary expertise" including sustainability consultants, procurement and contract specialists, and IT systems managers, reflecting the operational complexity of modern construction. In Stage 5, tacit knowledge was found prominent.

Stage 5 findings confirmed that buildability manifests most visibly during physical construction. Participants highlighted the importance of logistics planning, sequencing, and tacit knowledge transfer from experienced personnel. Specialist subcontractors were noted as critical actors in resolving on-site challenges. The success of this phase relies heavily on the robustness of earlier design decisions and collaboration among the key stakeholders. Three key themes emerged include contractor's central role, dual reliance

on tacit and codified knowledge, and knowledge pooling and collaborative discussions sharing tacit knowledge.

4.7 STAGE 6 – HANDOVER

Stage 6 marks the culmination of the construction process and the transition to operational occupancy. Although often perceived as a technical and procedural step, the findings reveal that this phase involves nuanced knowledge exchanges, significant specialist involvement, and a critical interface between design, construction, and end user operations. Respondents consistently referred to the need for dedicated professionals such as handover specialists, life safety consultants, MEP and low voltage engineers, and commissioning experts. For instance, R1 elaborated on the structured presence of "handing over specialists" whose expertise lies in ensuring functional integrity, testing, and life safety compliance of technical systems. Moreover, there is strong emphasis on the importance of codified and tacit knowledge working in combination. Certifications, compliance documentation, warranties, and standards based testing form the codified knowledge backbone of this stage. As R12 noted, municipal councils, regulatory bodies such as CIDA, and sustainability certification frameworks like LEED are all active participants in confirming the quality, safety, and sustainability of the final product. Yet, this technical closure is insufficient without practical orientation and user education, particularly when novel technologies are introduced into building systems. Participant R4 identified this educational role as crucial, stressing that the end users must be adequately informed and trained to operate the built facility efficiently.

Another key finding is the emergence of new stakeholders during this phase. For example, facility managers, asset managers, owner operators, and end users. These stakeholders were less visible in earlier stages but have now become central to the ongoing performance and maintainability of the building. Notably, some participants like R10 expressed a sense of limited agency at this stage, asserting that "*you're unable to do anything by the time the project reaches handover".*

This stage reveals the complexity of transferring the building from project teams to end users. Participants highlighted the role of handover specialists, particularly in commissioning safety systems and digital networks. Certification bodies and municipal councils' involvement in issuing final compliance documents was highlighted. Participants emphasised the importance of life safety consultants, knowledge transfer mechanisms, and client education, especially where novel technologies are introduced. Four key themes emerged under this stage as the specialist led nature of the handover process, documentation and compliance, the importance of codified and experiential knowledge working in tandem, and limited agency for knowledge sharing.

4.8 STAGE 7 – IN USE

Stage 7 shifts focus from construction to operational performance, user experience, and long term asset management. The findings reveal that buildability does not end at handover but continues through use based learning and operational feedback. End users and facilities managers take centre stage in this phase. R12 and R3 emphasised the involvement of these stakeholders in maintaining the design's performance intent. R1 noted that "*the specialist could even be the end user*!" highlighting how operational insights can reveal issues overlooked during earlier phases. Contractors may remain involved post handover through warranties and support services (R12). According to R4,

modern buildings often feature advanced technologies, but users may lack the digital skills to operate them fully. R4 and R12 recommended structured onboarding through user manuals, digital twins, and interactive training to bridge this gap. R3 added that involving facilities managers earlier in the process could reduce inefficiencies and improve lifecycle performance. R2 stressed the importance of lived experience and feedback stating, "*you might need to engage with the other stakeholders to fine tune the design*." R3 noted that architects and consultants often continue to assist post handover, indicating that professional responsibility extends beyond design and construction.

The final stage underscores buildability as a life cycle philosophy. Interviewees indicated that post-occupancy performance and usability are contingent on effective knowledge transfer, end user training, and responsive facility management. Further, in this stage, digital competency becomes more critical if the project comprises numerous innovative technologies. End users, facility managers, and maintenance teams emerge as new custodians of buildability. Key themes that emerged include harness specialist knowledge can reside with the end user, knowledge transfer and digital competency gaps, buildability as a life cycle philosophy, and feedback mechanisms.

5. BUILDABILITY MOMENTUM CURVE

The Figure 2 illustrates the momentum of buildability across the RIBA Plan of Work stages. It represents the intensity and nature of buildability contributions over time, integrating findings from Stages 0 through 7. Thematic analysis embedded in phenomenological research philosophy lead to creation of the buildability momentum curve. The curve shows that buildability is often underdeveloped in early design due to limited contractor involvement but becomes more prominent in stages 3–5.

Handover and Use Stages 6 and 7 underscore the overlooked importance of commissioning, handover, and facilities management for ensuring project continuity and usability.

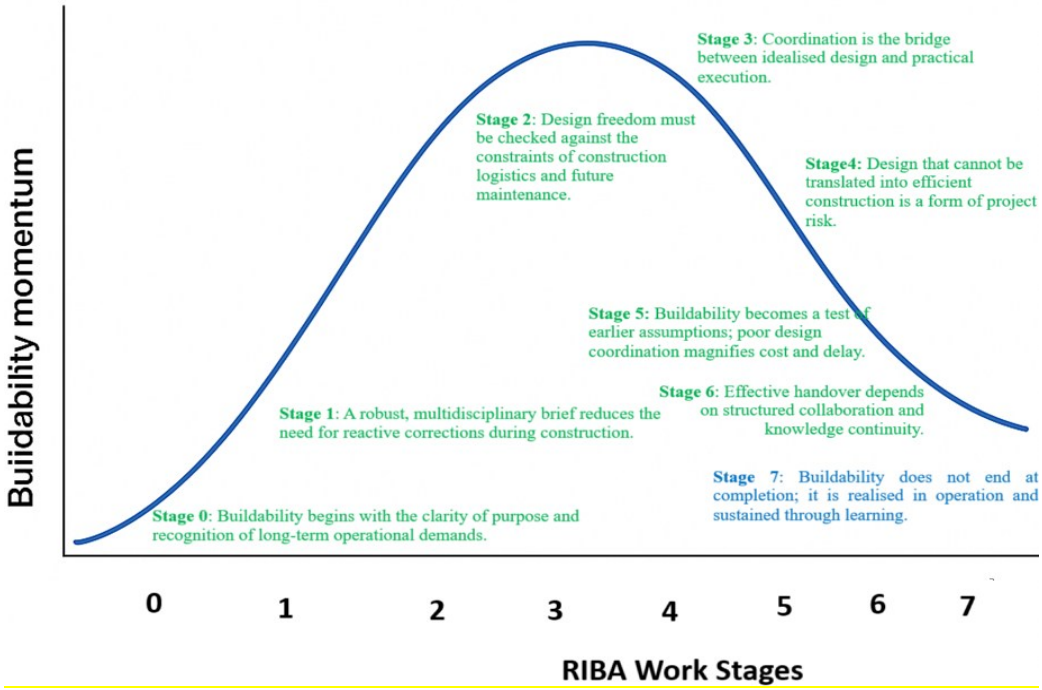

Figure 2: Diagram of the buildability momentum curve based on the RIBA Plan of Work stages

6. CONCLUSION

This research has provided a nuanced exploration into the dynamic integration of buildability across the RIBA Plan of Work 2020 stages, revealing a progressive accumulation of knowledge, collaboration, and decision-making that collectively fosters sustainable construction outcomes. By investigating stakeholder insights across all eight RIBA works stages, the study offers empirical evidence of the shifting nature and increasing significance of buildability considerations throughout a project's lifecycle. The findings indicate that while buildability begins conceptually in the early design stages, it gains substantial momentum in the technical design, manufacturing, and construction phases. These mid-stages are pivotal, acting as convergence points for tacit and codified knowledge from designers, contractors, and specialists, where theoretical planning transforms into practical execution. The contribution of the contractor and other implementation specialists becomes particularly critical from Stage 4 onwards, highlighting the importance of early contractor involvement and interdisciplinary collaboration. During later stages, particularly Stage 6 and Stage 7, the study finds that buildability evolves into maintainability and usability, necessitating structured knowledge transfer to facility managers, end users, and asset operators. Ultimately, this research positions buildability not as a static checklist, but as a momentum gathering complexity, insight, and impact across each stage of the RIBA framework. By capturing the voices and experiences of practitioners across disciplines, the study advocates for a more integrated, knowledge-driven, and strategically sustained approach to buildability that is essential for achieving resilient and sustainable construction outcomes in contemporary practice. The findings are limited to the ideas collected from the 12 professionals. The findings have practical implications for procurement strategies, project governance, and knowledge management systems within construction project teams. Additionally, the research bears the limitations arise from the specific data analysis methodology employed. Future research is encouraged to address these limitations by

developing stage specific buildability image models using AI and comprehensive buildability checklists to support implementation across all project stages.

BUILDING ENERGY DATA MANAGEMENT SYSTEMS IN THE WORLD: A REVIEW

Silva, S.D.R.Y [1], Madhusanka, H.W.N[2] and Kahandawa, K.A.R.V.D.[3]

ABSTRACT

Due to the growing number of buildings with higher population and urbanisation, tracking energy consumption in buildings is essential in reducing global energy demand and carbon emissions. For that, governments and energy-related international bodies have created many databases to collect data on building energy consumption and provide energy statistics based on that. This paper focuses on reviewing building energy databases in the world to study their policy implications and applicability in reducing building energy consumption. The qualitative approach was used in this study, and highly reputed and highly cited 09 databases were selected for the review. Among them, 04 databases provide energy benchmarks for buildings under different types of categories, while 05 databases provide energy statistics only. These databases allow government authorities to monitor the energy performance of buildings, determine tax credits and incentives for energy performance, rate the buildings and prioritise low-performing buildings for setting action plans. In addition, some of those have led to revisions of building codes and received the direct involvement of the relevant stakeholders through mandatory disclosure of energy data. Organisations also use these databases for marketing purposes, highlighting their high performance and allowing them to identify performance gaps. All the databases have been developed along with energy policies at the national and international levels. Compared to developed countries, energy databases are lacking in managing energy consumption in the national building stock. Especially, there is no energy database for the Sri Lankan building sector.

Keywords: *Building Energy Consumption; Building Energy Databases; Building Energy Data Management Systems; Building Performance Databases.*

1. INTRODUCTION

With the rapid population growth, building energy consumption has dramatically increased, contributing a significant portion of the global energy supply and demand over the past few years (Ali et al., 2020; Marinakis, 2020; Sun et al., 2020). An increase in energy demand directly affects the global Green House Gas (GHG) emissions, which has a significant impact on global climate change. Buildings contribute to 30% of global final energy consumption while accounting for 26% of global energy-related emissions by 2025 (Delmastro & Chen, 2023). However, numerous opportunities exist in buildings to

[1] Temporary Lecturer, Department of Facilities Managament, University of Moratuwa, Sri Lanka, silvar@uom.lk
[2] Senior Lecturer, Department of Facilities Managament, University of Moratuwa, Sri Lanka, nandunm@uom.lk
[3] Lecturer, Schol of Built Environment, Massey University, New Zealand, R.Kahandawa@massey.ac.nz

reduce energy consumption in buildings promoting a sustainable built environment. According to the IEA, energy efficiency improvements of buildings can decrease up to 70% of the energy-related emissions by 2050, and buildings will be 40% more energy efficient by 2040 (Ali et al., 2020).

Currently, there is a global tendency for a shift towards global exchange of building energy data, energy performance analysis, and building energy efficiency policies (Ali et al., 2020). Due to the development of technology massive amount of energy data is being generated in every aspect of buildings, and building systems are being digitised rapidly (Marinakis et al., 2020). This accumulated data can be effectively utilised to optimize power generation, predict electricity demand, discover electricity consumption patterns, and develop dynamic pricing mechanisms (Li et al., 2023; Zhou et al., 2016). Thereby, the building sector can effectively manage energy consumption, and the government can regulate the energy supply and demand effectively because it integrates the demand side management and Demand Response (Kathirgamanathan et al., 2021).

Data-driven approaches in building energy management have gained higher popularity over the past few years (Ahmad et al., 2018; Amasyali & El-Gohary, 2018; Kathirgamanathan et al., 2021; Li et al., 2023; Marinakis et al., 2020; Sun et al., 2020; Wei et al., 2018; Zhou et al., 2016). Data-driven approaches enable the prediction of energy consumption, which is imperative for improved decision-making on reducing energy consumption and environmental emissions and estimating the economic feasibility of further energy conservation opportunities (Wei et al., 2018). In addition to that, according to Mathew et al. (2015), empirical energy data has a wide range of potential in energy efficiency, assessment of energy policies, energy management and energy planning. Further to the authors, comprehensive energy databases can consolidate data throughout the industry, reducing the data collection cost, creating new opportunities to analyse building energy data and accessing many stakeholders. Large-scale empirical building energy data provides benefits to the government, stakeholders in the energy industry, investors in energy efficiency and policymakers (Luo et al., 2021).

Therefore, empirical building energy databases play a key role in supporting national-level energy policy assessments. Some of the databases record asset data and in-depth energy use as a representative sample of different building stocks (Ye et al., 2019). Those databases aim to keep datasets for energy planning and forecasting purposes. However, they provide summary statistics of the national building stock. To reduce the energy consumption and environmental performance of the building stock, governments set energy and environmental policies (Shen et al., 2020). To make informed decisions in setting national building energy policies, some governments are monitoring the energy consumption of their building stock (Luo et al., 2021). It helps them to identify the effectiveness of the policies and initiatives to identify which policies provide more benefits, to invest wisely in implementing those policies and initiatives (Carnieletto et al., 2019).

However, there is a limitation in the literature focusing on the policy implications of building energy data management systems in the world. Therefore, this study focuses on reviewing existing building energy data management systems to assess how they have been used to achieve sustainable development goals and energy policies at the international level, regional level or country level. In this paper, existing energy databases are reviewed on the data collection methods, outcomes of the databases, applicable

policies and national-level initiatives, and how they support to achievement of the intended outcomes of the energy policies. In addition to that, this paper discusses the level of usage of energy databases in achieving energy management policies in different countries.

2. METHODOLOGY

A qualitative, descriptive review approach was used in this study to evaluate existing building energy data management systems that have been implemented in different countries and global level. The main objective of this research is to review the structure of the database, types of energy data provided by the database, functionality, insights they produce, and the role of these systems in supporting organisational and national-level energy policies. Mainly, two primary sources were used for the data collection for this study. Google Scholar was used to access scholarly literature such as journal articles and conference papers that address specific energy data platforms and the policy implications of those data platforms. In addition to that, up-to-date information regarding building energy data platforms was collected from the official websites of the respective organisations.

Both technical details and real-world examples of system applications were provided by these sources, allowing to conduct a comprehensive review of the purpose, design, and output of each platform. When considering the selection criteria, energy data platforms, databases or systems that are publicly available or well-documented were selected for this study. Even though more than 50 building energy databases are available in the world, globally and regionally highly recognized and highly cited databases were selected for this study due to limitations in time and publicly available data. Only 09 databases were examined for this study. All the databases or platforms were reviewed to identify the type of energy data collected and displayed, such as electricity consumption, air pollution, energy performance etc, data sources used for the data collection, types of analytics or findings presented, target users and role in supporting energy policies at the national and international level.

Since the data was collected through publicly available content from websites and scholarly literature accessible through Google Scholar, some systems with restricted access or limited documentation may not be represented in this study. This study is based on the sample of energy databases at the international level, regional level or country level.

3. REVIEW OF EXISTING BUILDING ENERGY DATABASES

Due to the climate change impacts, governments are struggling to improve the lives of people while improving energy efficiency to reduce fuel poverty and fight climate change (Shen et al., 2020). Different governments, professional bodies, international organizations and interest parties in the energy industry have introduced more policies, initiatives, technologies and methods to improve energy efficiency to combat the climate change impact (Ye et al., 2019). However, it is important to identify the best solution that works best for each consumer by monitoring their consumption patterns closely (Buchanan et al., 2014). For that, different governments and international organizations

have introduced databases to monitor the energy consumption of the building stock and provide benchmarks for energy performance in buildings.

Figure 1 shows the country-wise evolution of building energy databases. An upward trend can be identified in the building energy database development during the 2000-2025 period. In the early 2000s, a slow growth in energy database development in the building sector. At the initial stage required data for building energy policy formulation was collected through one-time national surveys and manual data collection methods due to limited digital integration. Energy performance certification mandates and energy performance benchmarking come into the picture slightly. However, there have been a few local pilot projects and academic databases. A significant policy-driven expansion can be identified during 2005-2010. Several government mandates were set with the requirement of standardisation and mandatory reporting. UK NEED (2006), Australia NABERS (2007) and ENERGY STAR Portfolio Manager (2009) are a few examples of databases that originated in this period. Web-based reporting was initially introduced in this period.

A digital and open data boom can be identified with the evolution of big data technology, system integration and research collaborations to enhance building energy performance to address climate change during 2010-2015. THE US BPD (2011), the EU Building Stock Observatory (2013), and China's National Monitoring System (2013) were developed in this period. In addition, a shift from surveys to real-time data can be identified during this period with the development of smart technologies and the Internet of Things (IoT). With the development of Artificial Intelligence (AI), Machine Learning (ML) and the concept of smart buildings, AI-driven analytics such as anomaly detection and load forecasting took place within the building sector during 2015-2020. Most advanced energy databases such as ASHRAE GEPIII (2019), Singapore Benchmarking Portal (2020) and Dubai DEWA (2020) were established in this period. Especially, private sector adaptation to use these databases for real estate ESG reporting has a positive impact of these data-driven approaches. With the real-time monitoring requirements and net-zero targets, more advanced data sharing platforms are being introduced after 2020. ISO 52120 was introduced in 2025 as the first global data exchange standard. Especially, real-time dashboards have replaced static reports.

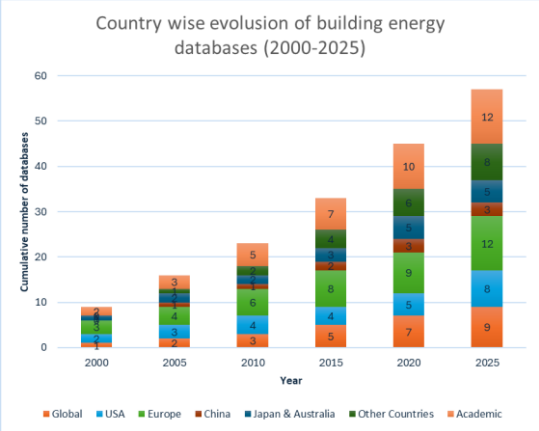

Figure 1: country wise evolution of building energy databases

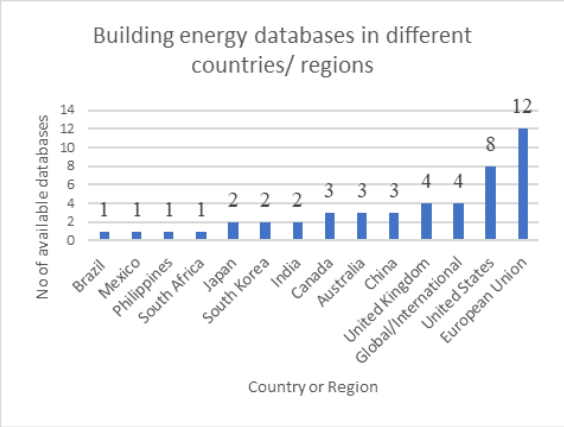

Figure 2: Building energy databases in different countries/ regions

Figure 2 shows the available building energy databases in different countries. According to Figure 2, the highest number of building energy databases is in the European Union, a result of the EU Energy Performance of Buildings Directive (EPBD) mandates and cross-border climate commitments, while the second heights number of databases is in the United States. The United Kingdom has 4 databases, and another 4 databases cover multiple countries in different regions. Canada, Australia, and China have 3 databases in each, while India, South Korea and Japan have 2 databases in each. According to Kumanayake and Luo (2018), the building sector contributes to 35% of the national energy consumption. However, in developing countries, there is a very small amount of energy databases covering their building stock due to limited funding for data infrastructure development, weak policy enforcement, and fragmented stakeholders lacking collaboration between governments, researchers, utility companies and building owners. Therefore, less popularity can be identified in building energy databases in developing countries.

Some of the leading and highly recognised energy databases are reviewed below.

- Energy in Buildings and Communities (EBC) Annex 70-International Energy Agency (IEA)

IEA has created a building energy database called Energy in Buildings and Communities (EBC) Annex 70, focusing on the analysis of energy use of buildings in 15 countries from 2017. It provides an international collaboration of governments, researchers and industry experts in the world working to develop methods to improve empirical data on the energy demand of the building stock. To study the energy demand of the building stock, Annex 70 collects data on features of buildings, energy consumption, characteristics of the occupancy, user behaviours, information on building systems and building morphology. The annex compares building energy data to address the energy performance gaps and assists businesses in the creation of low-energy and low-carbon solutions (Ruyssevelt & Hamilton, 2017).

- ENERGY STAR Portfolio Manager

ENERGY STAR Portfolio Manager collects benchmarking data in the United States and Canada buildings and assigns a rating for each building type. ENERGY STAR Portfolio Manager can be identified as a resource management tool which allows building users to benchmark the energy use of any type of building. Currently, more than 25% of US commercial buildings are being benchmarked in ENERGY STAR Portfolio Manager, which serves as the national benchmarking tool in Canada. Since every building type has been assigned a rating called the ENERGY STAR score, it compares the energy performance of the building with similar buildings nationwide, normalised for operating conditions and weather (Vaidya et al., 2009). To benchmark the buildings, only energy bills and basic information about the building are required. Apart from energy, ENERGY STAR Portfolio Manager allows benchmarking of water consumption, waste generation and GHG emissions.

- US Department of Energy-The Building Performance Database (BPD)

US BPD is one of the largest energy-related databases dedicated to commercial and residential buildings in the United States. It collects data from the government, energy efficiency programs, private companies and building owners. The collected energy data is available to the public (U. S. Department of Energy, 2025). It allows the users to

explore the data across different real estate sectors and regions and compare operational conditions and various physical characteristics to clearly understand the performance patterns and conditions in the energy market (Ye et al., 2019). Users can develop and save custom peer group datasets using different types of variables such as building types, locations, sizes, ages, equipment, operational characteristics and more. Furthermore, any two peer groups can be compared by users using statistical or actuarial methods (Tian et al., 2021).

- Commercial Buildings Energy Consumption Survey

The Commercial Buildings Energy Consumption Survey is managed by the US Energy Information Administration (EIA) (*Regional dashboards and data*, 2015). It serves as a sample survey in the US that collects data about US commercial building stock, including building characteristics that affect energy consumption, and energy usage data such as consumption rates and energy charges (Ye et al., 2019). It covers all the commercial buildings and schools, religious buildings, and hospitals, which might not be considered commercial buildings, with conventional commercial buildings such as shops, warehouses, restaurants and office buildings. It offers open data sets to manipulate energy data within the US energy industry, interactive dashboards to provide energy statistics and energy forecasting tools. EIA provides energy statistics for energy production, consumption, pricing, etc., related to building energy data. Stakeholders in the energy industry and policymakers are allowed to use this data to make informed and data-driven decisions (Department of Energy, 2025).

- EU Building Stock Observatory

The EU Building Stock Observatory is a comprehensive database on energy performance in buildings European Union. The main objective of this database is to provide reliable and transparent data and information on energy usage in buildings in European countries. It helps to monitor the current energy policies and measures in the European Union and helps future policymaking in building energy management. Building Stock Observatory covers a wide range of energy-related topics and provides building-related information such as building stock, energy usage, building elements and technical systems installed in buildings, certificates on energy performance, renovation rates and zero-energy buildings, energy poverty and investments in energy-saving buildings (Gevorgian et al., 2021). The EU Building Stock Observatory was introduced in 2016 along with the Clean Energy for All Europeans package. It is also aligned with the LIFE Clean Energy Transition subprogramme. In addition to that, the EU Building Stock Observatory is part of a broader policy strategy to support the implementation of the Energy Performance of Buildings Directive (EU/2024/1275) and the Energy Efficiency Directive (EU/2023/1791) (European Commission, 2025).

- National Energy Efficiency Data Framework (NEED) – United Kingdom

The National Energy Efficiency Data Framework (NEED) was established to gain a greater understanding of energy use and efficiency in both residential and non-domestic facilities in Great Britain. It provides gas and electricity consumption data in domestic and non-domestic buildings. The important thing is that the information related to energy efficiency measures installed in buildings is collected along with the energy consumption data. In addition to that, data related to characteristics of the property, such as floor area, property age, property type, occupancy data, geography, and socio-demographic data are

collected. Thereby, NEED evaluates the energy savings arising from the installation of energy-saving measures by comparing energy and gas consumption before and after the installation of the energy-saving measure. This database provides the largest available database to analyse gas and electricity consumption and the impacts of energy efficiency measures. After calculating the annual energy consumption, buildings are rated based on their efficiency of the buildings (Department for Energy Security and Net Zero, 2025).

- Australian NABERS (National Australian Built Environment Rating System)

NABERS is a voluntary performance-based rating system which evaluates the overall environmental performance during the operation of various types of buildings. This acts as a building rating and serves as the database in the building sector in Australia by storing data, providing valuable statistics from 1999. Further, it allows buildings to accurately measure, understand, and communicate the environmental performance of buildings while identifying areas for cost savings and future improvements. NABERS rates buildings from one to six stars for building efficiency categories such as energy, water, waste, and indoor environment. Building owners must submit their building data in an Excel spreadsheet provided on the NABERS website after creating a user account. NABERS provides a maximum amount of energy and water that buildings can use to achieve the desired rating. Benchmarks are updated every five years according to the updated data. Currently, this benchmarking tool and database have been launched in the United Kingdom and New Zealand as well (NABERS, 2025).

- India's Energy Efficiency Data Portal

The energy efficiency data portal of India was developed by the Bureau of Energy Efficiency under the aegis of the Ministry of Power in India to produce reliable energy data regarding the supply and demand of energy in different sectors within the country. Collected data is used to publish the National Energy Data Survey and Analysis report, covering both the supply and demand sides. In addition to that, it provides energy-saving and emission reduction statistics across the country by implementing energy-saving projects. There is a separate tab called BEEP stands for National Building Energy Efficiency Program. It provides a comprehensive database of the results of energy efficiency improvement projects across the country (Bureau of Energy Efficiency, 2023).

- TABULA and EPISCOPE

TABULA is a topology approach which has been created to assess the building stock energy, while EPISCOPE is an energy performance indicator tracking scheme for the continuation of the optimisation of the refurbishment process in the building stock in the European Union. Each topology consists of a classification scheme that groups the building stock according to their size, age and other parameters, and it gives a set of example buildings representing these building types. TABULA was funded by the European Commission's Intelligent Energy Europe (IEE) program, and EPISCOPE was established to follow up on the TABULA program to monitor renovation strategies. A reference building is created in TABULA for different building types in the participating countries. To create the reference building, construction characteristics, details related to geometry and layoutsand other related details of energy performance of retrofit scenarios are collected (Stein et al., 2016).

Table 1 shows the summary of the selected building energy databases.

Table 1: Summary of the building energy databases

Name of the Database	Aim of the database	Related policies and initiatives	Policy impact	Organizational impact
Energy in Buildings and Communities (EBC) Annex 70	Developing standardized methodologies to compare international building energy data to support evidence-based policymaking	EU Energy Performance of Buildings Directive (EPBD), Energy in Buildings and Communities Program	Supported energy-saving calculations for tax credits. Improved energy performance certification methodologies	Allows universities to harmonize global building energy datasets. Building automation service providers aligned their products with Annex 70's performance benchmarks.
ENERGY STAR Portfolio Manager	Enable benchmarking and tracking of energy/water use in buildings to drive market-based efficiency improvements.	Energy Policy Act of 2005 (EPAct 2005), Energy Independence and Security Act (EISA) of 2007	Used for mandatory energy benchmarking of buildings in 25 cities in the US. Became an industry standard for the real estate sector.	Some real estate companies used it for ESG reporting and lease agreements including clauses mandating ENERGY STAR scores. Some case studies show that Automated benchmarking reduced manual data entry by 40%.
Building Performance Database (BPD)	Collect performance data to identify retrofit opportunities and validate energy codes.	Energy Policy Act of 2005 (EPAct 2005), Energy Independence and Security Act (EISA) of 2007	Led to revisions of building codes. Adjusted tax credits for energy retrofits. Supported Chicago's Building Energy Use Reporting Ordinance.	Some companies use BPD to justify ROI calculations for clients. Sustainability authorities use BPD to audit compliance with Local regulations.
Commercial Buildings Energy Consumption Survey	Provide statistically representative data on US commercial building energy use for national policy and research.	Energy Policy Act of 2005 (EPAct 2005), Energy Independence and Security Act (EISA) of 2007	Started with the US Net-Zero Commercial Buildings goal and led to informed energy code updates. Supported design efficiency incentives for utilities.	Some architecture forms use this to validate energy models in the early design stage.
National Energy Efficiency Data	Link energy use data with socio-demographic factors to target fuel	Directly related to low-carbon policies in the UK	Identified households lack clean energy for subsidies. Targeted intervention using consumption patterns for smart meter installation.	Social Housing Providers used NEED to prioritize retrofits in residential buildings. Energy Suppliers developed targeted efficiency offers using poverty maps.

Name of the Database	Aim of the database	Related policies and initiatives	Policy impact	Organizational impact
Framework (NEED) – UK	poverty and efficiency programs.		Net-zero planning for 2050 decarbonization targets.	
EU Building Stock Observatory	Monitor the EU-wide building stock to track progress toward climate goals	Energy Performance of Buildings Directive (EU/2024/1275) and the Energy Efficiency Directive (EU/2023/1791)	Prioritized low-performing buildings for EU funding. Used to track progress towards 2030 energy targets. Used to map regional disparities in building energy efficiency.	Construction Companies have referenced it to market insulation products. City Governments used it to identify retrofit zones.
TABULA and EPISCOPE	Create standardized building typologies to simplify energy retrofit planning and cost-benefit analysis.	European Commission's Intelligent Energy Europe (IEE) program	Standardized building envelope design in EU buildings. Supported to establishment building energy roadmap policy in Germany and Vienna's 2040 Climate Roadmap.	Retrofit companies use TABULA archetypes for modular facade solutions. Some banks have introduced loan schemes which require TABULA-based energy audits.
Australian NABERS	Rate buildings based on actual operational performance to drive market competition for efficiency	Supports to achievement of the net-zero energy targets by 2050	It became a mandatory disclosure. Higher added value for high-rate buildings. Used for national climate policy implementation.	Some companies increased asset values via NABERS-driven upgrades. Some companies automate NABERS compliance for 80% of rated buildings.
India's Energy Efficiency Data Portal	Support compliance with India's Energy Conservation Building Code (ECBC) and PAT scheme for industries	National Building Energy Efficiency Program	Supported building code revisions. Used for retrofit targets in several estates. Became an industry benchmarking program.	Some companies use portal data to comply with national energy regulations. Some manufacturers reference portal data for HVAC sizing tools.

According to the analysis of the different building energy databases, Energy in Buildings and Communities (EBC) Annex 70 serves several countries in different regions, while other databases serve only a specific country. Some of the databases such as BPD, Commercial Buildings Energy Consumption Survey, EU Building Stock Observatory and India's Energy Efficiency Data Portal provide merely statistics related to building energy while some of the databases such as Energy in Buildings and Communities (EBC) Annex 70, ENERGY STAR Portfolio Manager, TABULA and EPISCOPE, and Australian NABERS act as an energy benchmarking tool for building while providing energy statistics for building stock. By providing benchmarks, buildings are given performance targets and are measured for the energy performance of each building compared to similar types of buildings.

When considering the data collection method, some databases collect data from surveys such as the Commercial Buildings Energy Consumption Survey while others collect data from other national-level or regional-level databases. Energy in Buildings and Communities (EBC) Annex 70 collects data from universities and national-level institutes by creating a collaboration with multiple organizations representing each country.

Currently, most of the databases cover the effectiveness of energy-saving initiatives and energy retrofitting, along with recording energy generation, consumption and pricing. Energy in Buildings and Communities (EBC) Annex 70, National Energy Efficiency Data Framework (NEED) – UK and India's Energy Efficiency Data Portal are examples of those types of databases. It helps to identify the effectiveness of energy-saving measures and building retrofits for different types of buildings (Carnieletto et al., 2019). To achieve sustainable development goals by easy access to information, some databases have provided free access and publicly available datasets for parties who are interested. India's Energy Efficiency Data Portal, EU Building Stock Observatory and Commercial Buildings Energy Consumption Survey are some examples of freely accessible databases. However, some databases still require paying to get energy data and have taken actions to restrict unauthorized access to maintain data confidentiality. ENERGY STAR Portfolio Manager and Energy in Buildings and Communities (EBC) Annex 70 require user accounts to get datasets from the database.

All the above building energy databases aim to compare the energy performance of different buildings and to support evidence-based policy making. Furthermore, some databases such as NEED and ENERGY STAR Portfolio Manager aim to identify energy-saving potentials and retrofitting opportunities in buildings. Moreover, NEED links energy use data with socio-demographic factors to identify target groups with fuel poverty. Meanwhile BPD and Commercial Buildings Energy Consumption Survey aims to validate existing building codes and revise existing policies and mandates based on the statistical conclusions of the collected data. According to Table 1, diversified stakeholders are considered by every database, such as national and local governments, national and international organizations, researchers, building owners, utility companies, architects, engineers, energy auditors, financial companies, real estate companies, retrofitting companies, and the community.

When considering the policy implications, all the above databases are governed by government bodies or international energy authorities. They directly aligned the outputs given by the databases to verify the benefits of the policies and to measure how well organizations adopt those policies. In addition to that, these energy databases enable

organizations to enhance their market value using benchmarks and comparing building energy data, such as ENERGY STAR Portfolio Manager and Building Performance Database. Some of the databases focus on the specific type of building stock, such as the National Energy Efficiency Data Framework (NEED) – UK, while other databases cover the entire building stock. However, they provide statistics for specific building types using collected data.

With the introduction of some of these databases, such as ENERGY STAR Portfolio Manager, Building Performance Database (BPD) and Australian NABERS, mandatory disclosure of energy data became an industry standard in the real estate sector. Energy in Buildings and Communities (EBC) Annex 70 and Building Performance Database (BPD) have been used to calculate the energy saving for tax credits. In addition to that, energy performance certification methodologies were improved with the use of collected data by Energy in Buildings and Communities (EBC) Annex 70. Building Performance Database (BPD), Commercial Buildings Energy Consumption Survey, India's Energy Efficiency Data Portal and Australian NABERS led to revisions of building codes. Specifically, NEED was used to identify the targeted groups with energy poverty to make required interventions and set decarbonization targets by 2050. Furthermore, the EU Building Stock Observatory identifies low-performing buildings for EU funding. It highlights the contribution of these databases in identifying energy performance gaps within the building industry. The EU Building Stock Observatory, TABULA and EPISCOPE, Australian NABERS, and India's Energy Efficiency Data Portal have directly supported to formulation of energy policies and climate policies. In addition to that, these databases have supported tracking the energy targets.

As a result of these databases, building service providers tend to align their products to meet industry benchmarks. Furthermore, real estate companies use these benchmarking and energy-related data for ESG reporting, and automated data platforms have reduced the manual paperwork in obtaining energy performance certification. Furthermore, utility providers have introduced efficiency offers for their customers based on reported data. In addition, these databases and mandatory reporting allow companies to identify performance gaps and retrofitting opportunities in their buildings to become more energy efficient.

Although the adaptability of building energy databases is becoming popular in developed countries, the usage of building energy databases is still fledgling in developing countries. Similarly, there is no dedicated energy database for buildings in Sri Lanka to monitor the building energy consumption to make informed decisions to create energy policies for buildings. Therefore, to achieve the intended outcomes of the national energy policy in Sri Lanka, a comprehensive building energy database is a key element that should be introduced to the building sector. Therefore, further research can be conducted on developing a building energy database in Sri Lanka.

4. CONCLUSION

Since buildings contribute a significant portion of total energy consumption, a higher consideration has been given to reducing building energy consumption by closely monitoring the adaptation of energy policies and initiatives by the governments. This study reviews the building energy databases in the world to identify their policy implications and applicability in reducing energy consumption in buildings. Nine

building energy databases were studied. Among them, Energy in Buildings and Communities (EBC) Annex 70 covers multiple countries acting as an international building energy database, while other databases cover only a specific country or region. Four databases act as benchmarking tools, while 5 databases provide only energy statistics. Surveys and other energy databases are used as the data collection methods. There is a tendency to evaluate the efficiency of energy retrofitting in buildings; while monitoring energy consumption, all the databases collect data on energy-saving mechanisms that buildings use to reduce energy consumption. Currently, most of the databases allow users to access energy data freely to assist them in informed decision-making in building energy management. All the databases have been established along with a specific energy policy or an energy management program to measure and validate the effectiveness of the introduced policies. Even though there is a growing tendency to manage building energy databases at the national level in developed countries, a limited approach can be seen in developing countries in this context. A building energy database is still lacking in the Sri Lankan context, even though a proportion of the national energy is consumed by the building sector. Therefore, future researchers can focus on developing an energy database for buildings in Sri Lanka.

BUILDINGS DESIGNED FOR SYSTEMIC CIRCULARITY: A COMPREHENSIVE REVIEW OF METHODOLOGICAL TAXONOMIES

Prince Antwi-Afari[1], Daniel Oteng[2], S. Thomas Ng[3], Frank Ato Ghansah[4] and Zhikang Bao[5]

ABSTRACT

Circular economy (CE) principles have been appraised as the requisite approach to enhance buildings and construction process to achieve sustainable development. Hence, architects and other construction professionals have been urged to adopt the CE principles in design thinking, supply chain systems, production, operation, and end-of-life activities of buildings. However, as much as CE principles could be seen subjectively to benefit the environment, it is incumbent to determine and document this empirically to propel its seamless adoption and enforcement. Therefore, extant studies have proposed several methods, metrics, and indicators to assess the environmental impact, recovery, technical, cost, systems, and recyclability potentials of buildings designed for total circularity. Nonetheless, the complexity of CE requires that such assessment should consider the integration of different methods that should be able to assess the different dimensions of the lifecycle of a circularly designed building. In this study, a thorough systematic review was conducted to explore the existing means of measurement and propose a comprehensive methodological approach for assessing buildings designed for systemic circularity. The proposed approach should enhance CE methodological development and guide construction professionals and building designers in the effective adoption of CE principles throughout building lifecycles to attain sustainable development.

1. INTRODUCTION

The fate of most existing building structures at their end-of-life have been predetermined for landfill due to adopted construction process. The traditional construction process follows a take-make-dispose design thinking approach whereby buildings are not designed with reusability of parts or materials in mind (Hossain et al., 2020). This approach has led to the exorbitant building and demolition waste which the construction industry is currently facing. To circumvent this approach and reduce the negative effects of building across its lifecycle, a new design thinking which embeds circularity and sustainable principles should be upheld (Ellen MacArthur Foundation, 2015; Antwi-Afari et al., 2023).

Extant studies have shaped the direction of contemporary building design thinking to incorporate key sustainable and circularity principles such as adaptability, manufacturability, assembly, reusability, systemic circularity, flexibility, and cost among others (c.f., Moraga et al., 2019; Attia & Al-Obaidy., 2021; De Silva et al., 2023). Hence, there has been an influx of new design strategies and models which helps construction stakeholders to target the sustainability agenda. However, how to evaluate the extent of systemic circularity of a building or component designed through these design thinking approaches needs to be identified. Systemic circularity encompasses the assessment of buildings entire production system and goes beyond the sustainable principles adopted within the design, manufacturing and construction process. Thus, it includes the adopted business models, system conditions and reverse cycles together with the key performance indicators under each of these building blocks (Antwi-Afari, 2023).

To assess buildings designed with sustainable or circular thinking, this study conducted a systematic review of extant literature to identify the existing methods, tools, metrics or indicators. The current study differs from existing review studies (c.f, Antwi-Afari et al., 2022; Oluleye et al., 2023) because of the broad perspective of not limiting the literature search to only one or few sustainability indicators, also, different methods and metrics as far as they fall within the scope of the study were considered in the study. To this end, this study was conducted to evaluate the intellectual core and key methods needed to evaluate buildings design for systemic circularity. The rest of the manuscript is as follows: the next section provides details on the methods adopted for reviewing extant literature. The key findings of the methods, metrics, indicators or tools for assessing buildings' systemic circularity is also presented. Then the discussion of these methods and conclusions and further research sections are also shown.

2. METHODOLOGY

This study adopted a critical review approach to carefully analyse all the extant literature. Based on different review methods in Grant and Booth (2009)'s studies, critical reviews help researchers to identify discrepancies in existing literature and resolve ideas by finding solution rather than merely highlighting gaps. A four-stage approach was used to conduct this critical review. To obtain the papers used for the study, a detailed advanced search was conducted in Scopus with relevant words such as methods, metrics, indicators and building construction and limited to the last decade.

The search string "circular metrics" OR "Circularity Indicator" OR "metric" OR "circular methods" OR "sustainable metrics" OR "Circularity Assessment" AND "building construction". Scopus was chosen as the preferred database because it has a wide range

of reach and a powerful data control and quality analytical tools (Oteng et al., 2021). A total of 143 documents were retrieved from the advanced search. Further analysis of the abstract, keywords and the title of the documents led to 99 obtained papers used in the critical review analysis. A thorough content review was done to cut down the papers even further for the content analysis. This led to the use of 17 articles which were considered as appropriate and detailed enough for such purposes. The overall 99 retrieved papers were also classified across predefined criteria such as scope, document type, year, materials used, citation count, and methods adopted.

The 17 articles selected for content analysis were then reviewed and their key findings concerning methods, metrics, indicators and tools for assessing buildings design for systemic circularity were identified and presented. Based on the in-depth content analysis, the key methods, tools, metrics, and indicators for evaluating buildings systemic circularity were discussed and a comprehensive methodological approach which could be adopted to enhance buildings systemic circularity were formulated based on extant literature.

3. FINDINGS

The year trends of the selected documents revealed that majority of the articles on methods for assessing the circularity of buildings were published in 2023 with more than two-thirds published after 2020 (Fig. 1). This matches the influx and popularity which circular economy (CE) was obtaining during and after the Covid-19 era. The need to rethink existing systems, achieve resilience and enhance innovation in the construction industry (CI) post-pandemic era increases the attention of researchers considering how to measure the improvements made to the circularity of buildings along its lifecycles.

The cited sources citation shows that of the selected documents, at least 23 received 0-20 number of citations on average. While more than 50 articles received more thana 20 citations but less than 41 citations. Hence on average, we can infer from the analysis that at least more than half of CE metrics, methods or measurement studies in the last decade had at least receive 40 citations. This shows the influence, relevance and impact of this research to the built environment and the scientific community. Hence, a more important reason to continue to research in this area to push the frontiers of knowledge in the key methods for assessing building circularity to reduce poor measurement and gauge the improvement done in building circularity correctly.

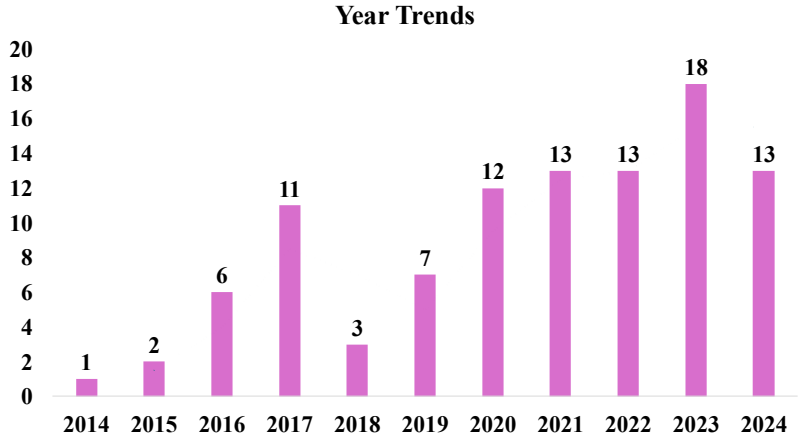

Figure 1: Year trends of CE methods for assessing buildings circularity

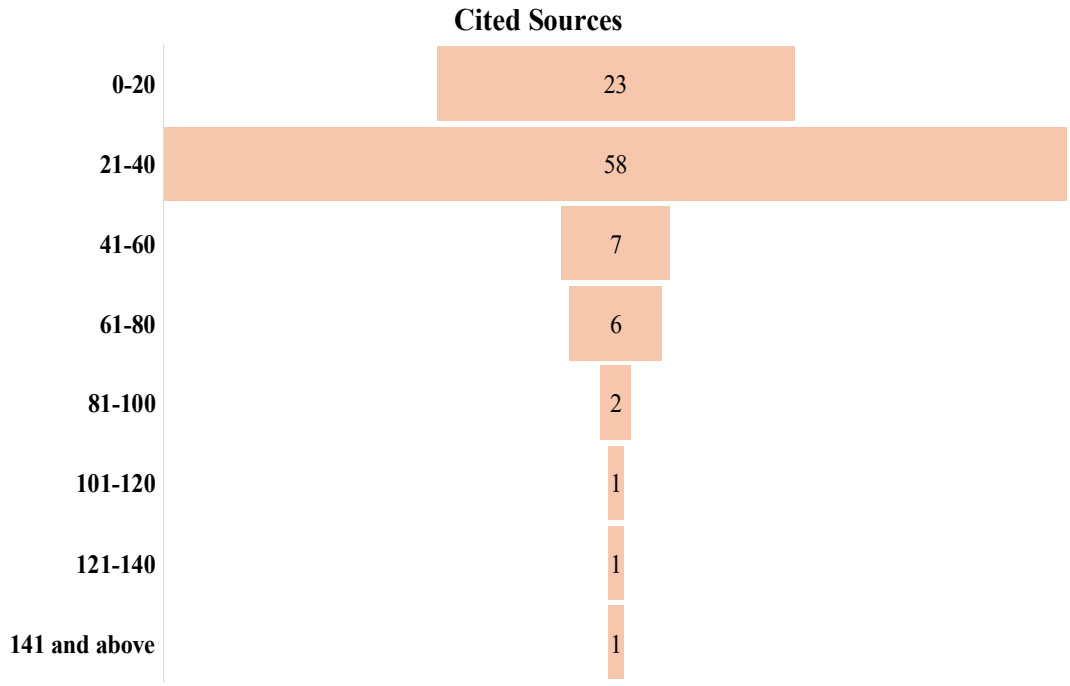

Figure 2: Cited source co-citation of selected articles

The selected documents used for the study were mainly peer-reviewed published journal articles from Scopus. This formed about 77% of the total number of articles with about 14% being peer-reviewed conferences. Since this study was looking at methods used for assessing building circularity, the key focus was on analytical articles with few very good review articles considered which formed about 6% of the selected articles. Book chapters were only 3% of the selected articles for this study.

The scope of selected articles helped to identify the focus of these articles. It was seen that most of the articles on CE measurement for building circularity looked at the materials level. Thus, concrete, steel, plastics etc. which formed 28.28% of all the selected articles. Case-specific articles were mainly studies which looked at different case scenarios of materials, buildings or projects. This formed 21.21% of all the selected articles. Component level such as slabs, floors, roofs etc. formed 13.13% of all the articles used in the critical review while 7.07% and 5.05% of the articles were focused on national or corporate level looking at circularity of buildings from business models and policies impact on decision making.

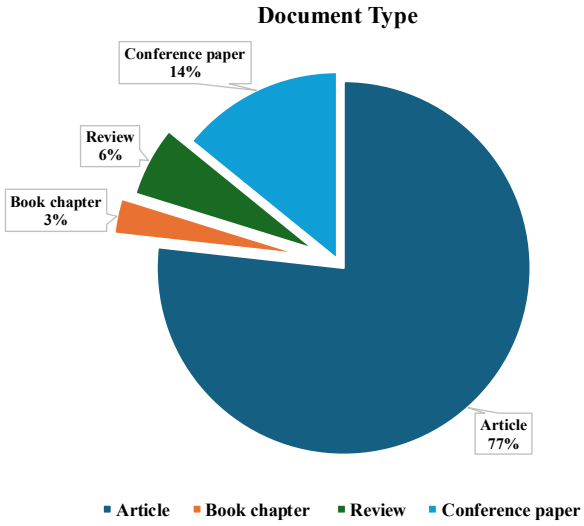

Figure 3: Document types of selected articles

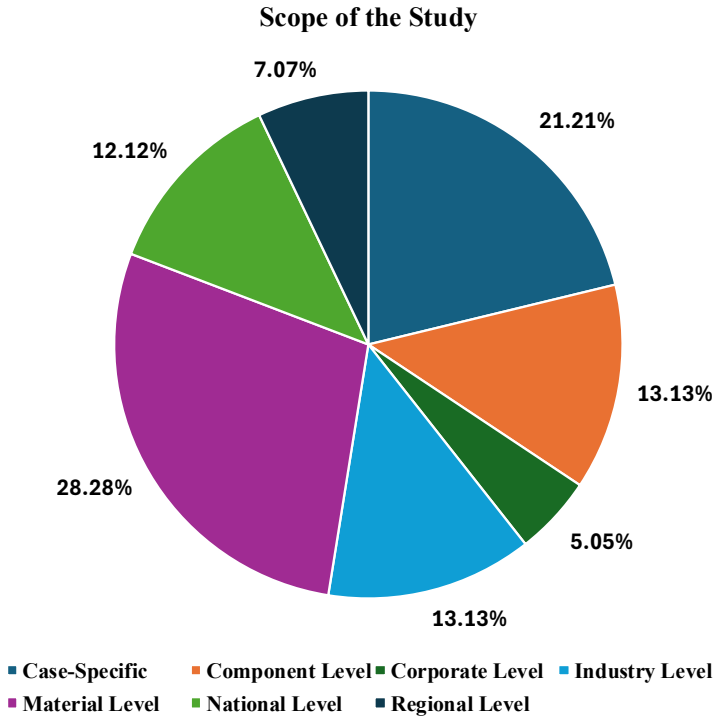

Figure 4: Scope of selected articles

The next analysis of the review was to consider the materials used for the analysis. About nine of the studies did not specify any kind of materials or did not provide any material usage details at all. These were mainly corporate or policy related studies which focused on improving existing building business models to be circular. Eight of the articles focused on wood and its derivates such as cross laminated timber, sawn timber, glue laminated timber and their usage for kitchen modules or other parts of buildings. Different kinds of materials were all considered in the extant literature. For example, steel (nine studies), concrete (nine studies), Paper (three studies), composite materials which encompass a reinforced concrete, engineered wood products and fibre-reinforced

polymers among others formed about 12 of the selected articles. Also, about nine of the studies looked at waste during construction and demolition of circular buildings and how the circularity at that phase is measured.

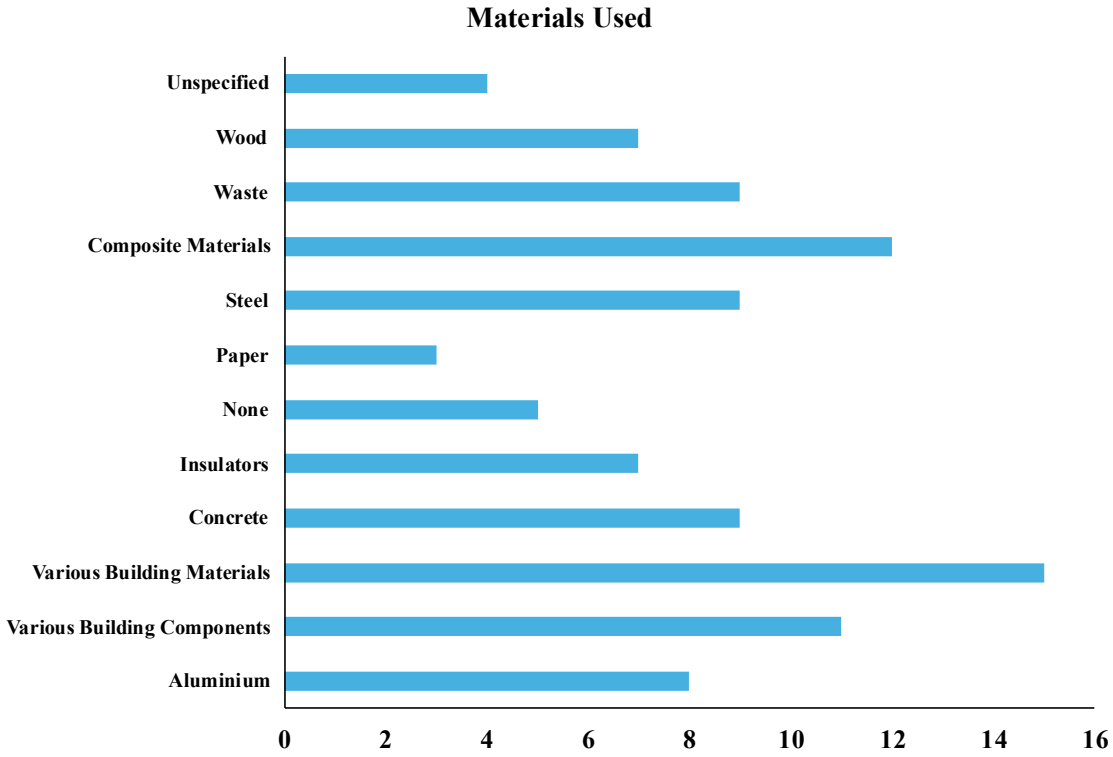

Figure 5: Materials assessed in the methods of selected articles

The last analysis in this section was to evaluate the methods adopted in extant literature for measuring the circularity of buildings. Aside from review articles which used document analysis (about five studies), the rest of the articles used some kind of method to assess the impact of materials along the environment, social, economic, technical, and systems dimensions. Most studies used only one type of method for analysis. For instance, lifecycle assessment (LCA) only was used to determine the embodied carbon impacts of materials, while building information modelling (BIM), LCA and multi-criteria decision-making methods (MCDM) were used to assess the decision-making models of circular designed buildings among others. The use of different methods enabled extant studies to evaluate the sustainability and circularity of different materials, decisions, processes and strategies of circularly designed buildings, materials, components and design guidelines for CE attainment in buildings.

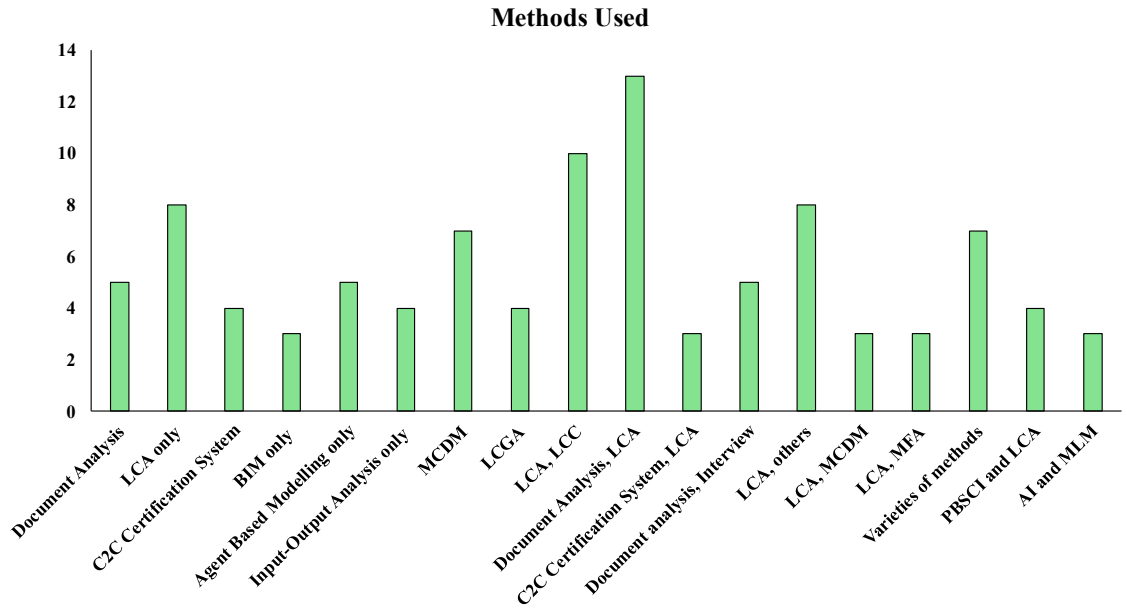

Figure 6: Methods used in the selected articles

4. DISCUSSIONS AND IMPLICATIONS

Different methods, metrics, and indicators have been adopted in extant literature to assess the circularity potentials of activities involved the in the lifecycle of building construction or circularly designed buildings. In this study, the key 17 articles used for content analysis were evaluated and the adopted methods, metrics and indicators used classified across the environmental, social, economic, technical, business and legislative dimensions.

4.1 ENVIRONMENTAL DIMENSIONS

To assess the environmental impacts of materials, processes or buildings designed to attain circularity, extant literatures have used indicators such as waste intensity indicators, longevity indicators, water intensity indicators, embodied carbon, embodied energy, resource output rate and resource duration indicators for environmental impact assessments (Franklin-Johnson et al., 2016; Romnee et al., 2019). Other methods such as LCA which look at assessing the environmental impact of materials across different midpoint and endpoint categories have been used to evaluate the environmental impact of plastic waste and end-of-life waste management (Hossain et al., 2021). To make decisions concerning circular buildings, Carvalho et al. (2021) used LCA and other methods to quantify the highest environmental impact performance among several different scenarios. LCA was also used together with input-output analysis to assess the cradle to grave embodied carbon and embodied energy of residential buildings designed to attain sustainability. The adoption of a hybrid form of LCA provided an improved means of quantifying buildings' material emissions (Zhan et al., 2018).

4.2 ECONOMIC DIMENSIONS

To assess the economic impact of buildings or materials designed for circularity, extant studies such as Magrini et al. (2021) and Malabi et al. (2021) adopted life cycle costing, material flow cost accounting, net present value, cost benefit analysis and life cycle sustainability assessment to assess circular waste and circular building components.

Indicators mostly used in examining the economic impacts of circularly designed buildings or materials includes investment cost indicator, cost of energy consumption, cost substitutive goods, sustainability financial incentives, transportation cost among others. Braakman (2019) adopted lifecycle cost (LCC) to assess the building circularity levels of a standard one-family house using design-oriented scenarios. The usage of LCC showed that increasing circularity of these buildings may not have substantial effect on its lifecycle cost, but as circularity increases, the LCC increases to almost double the initial cost. This provided an array to gauge circularity improvements to cost-effects of attaining circularity in buildings. Jansen et al. (2020) also proposed a circular economy LCC model for building components which helped to provide decisions on the most economic, but circular kitchen module to adopt taking into consideration product lifespan, interest rates and expected value retention percentages of the module.

4.3 SOCIAL DIMENSIONS

To evaluate the social dimensions of buildings designed for circularity, extant studies have used several indicators such as social fairness of building designs, health and safety during construction and stakeholder awareness among others as some of the key indicators. (c.f., Braungart et al., 2007; Toxopeus et al., 2015). Key methods or metrics adopted to measure the social aspects of circularity measurements include managerial indicators, organizational indicators, social circularity indicators, social life cycle assessment and cradle to cradle (C2C) assessment (c.f., Niero et al., 2017; Antwi-Afari et al., 2022). Fatourehchi & Zarghami (2020) adopted a social sustainability assessment framework to include social indicators in the measurement of sustainable residential buildings in Iran. The study identified that some key determinants of meeting the social aspects of a sustainable or circular building includes workplace health and safety, performance and flexibility at the workplace.

4.4 TECHNICAL DIMENSIONS

When assessing the technical dimensions of products designed for circularity, extant studies such as Geldermans (2016) Adams et al. (2017) and Alamarew et al. (2020) have proposed or used indicators such as material separability rate, usage level of recycled products, viable take back schemes, technological indicators and technical feasibility for examining the technical aspects of circularly designed materials or buildings. For metrics or methods, disassembly time and cost, end-of-life indices and predictive building circularity indicator (PBCI) have been used. For instance, Geldermans (2016) argued that to embrace full circularity measurement, technical, temporal, and social implications need to be calculated together with the economic and social impacts in formulating decisions.

4.5 BUSINESS DIMENSIONS

Circularity measurement encompasses consideration of the requisite business model enacted to enhance the reusability of building's materials or components across several lifecycles. Hence, measuring the circularity potentials of a product should include the business dimensions as well. Thus, whether the product (materials or building) has a reusability/recyclability plan and a circular business model to enhance its usage during the first cycle and reusability in subsequent lifecycles. Indicators such as supply chain indicators, and methods such as Agent Based modelling, system dynamics, multi-criteria decision-making methods among others have been proposed in extant literature to be

considering some of the business dimensions of CE measurement (c.f., Adams et al., 2017; Alamerew et al., 2020; Rossi et al., 2020).

4.6 LEGISLATIVE DIMENSIONS

To achieve systemic (total) circularity, a circularly designed product should also exhibit some key legislative dimensions such as responsible communication, meeting the required standards and performance solutions/minimum criteria of quality. Indicators such as strategy and policy indicators and methods such system dynamics, multi-criteria decision-making methods among others have been identified in extant literature to help in the evaluation of the legislative dimension of circularity (Magrini et al., 2021).

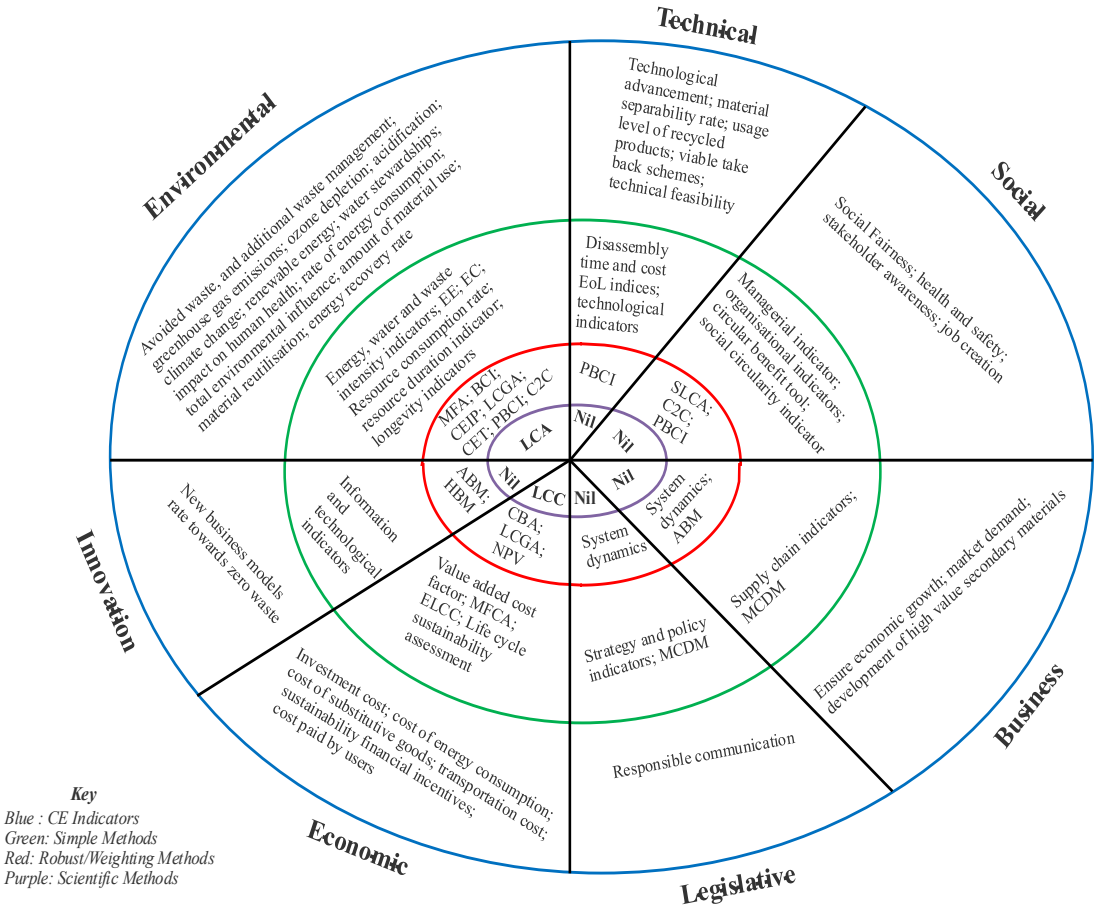

Fig. 7. Indicators, methods and metrics for circularity assessment. Adapted from Antwi-Afari et al. (2022)

4.7 AN INTEGRATED METHOD FOR ASSESSING BUILDING'S CIRCULARITY

To assess that a building or material has attain a total/systemic circularity, different impact dimensions should be evaluated such as the building's environmental, social, economic, business, technical, innovation and legislative dimensions. However, deducing from existing methods (Fig. 7) shows that none of the methods alone would be enough to assess the key dimensions of building's circularity. For example, LCA can give a clear indication of the building's environmental impact but its usage for assessing technical, cost and social dimensions is limited. LCC can also help in the economic quantification of different materials but its usage for environmental impact and social impact is

constrained. Multi-Criteria Decision-making methods could be used to evaluate some business and legislative aspects of product lifecycle systems, but its usage for environmental or economic impact assessment is inadequate.

Since total circularity of buildings will not only consider its environmental, economic or social impacts, but also its technical, systems and legislative considerations of the product lifecycle, there is the need to develop a robust assessment tool which will consider the requisite dimensions for a detailed assessment of the building's circularity. However, there is a problem with methods compatibility when integrating them as such some must still be assessed separately and infused into the integrated method calculation along the process or considered during the final decision-making process. This study proposes that, LCA, C2C and PBCI should be integrated into a methodological framework by combining their system boundaries, strength and indicators to assess the environmental, social, technical, business and legislative dimensions of circularly designed buildings.

To propose this integrated framework, LCA midpoint and endpoint indicators should be merged with that of C2C indicators and strengthened with an improved PBCI calculation to reduce the limitations of circularity assessments. Therefore, with LCA-C2C-PBSCI method, assessing the systemic circularity of buildings would consider the environmental, technical, social, business, legislation and innovation dimensions. Economic impacts could be added to the decision-making process using LCC or other economic impact indicators/methods and MCDM could also be used to help in the selection of the optimal circular scenario based on the assessed examples.

5. CONCLUSIONS

Assessing systemic circularity in building construction is critical for advancing sustainable practices and effectively integrating circular economy principles into the construction sector. Although numerous methods exist to evaluate circularity, a comprehensive, integrated approach that addresses multiple dimensions simultaneously remains underexplored. Existing research primarily focuses on isolated dimensions such as environmental impacts or economic assessments, neglecting a holistic view necessary for systemic circularity. Addressing this gap, the current study systematically reviewed existing methods, metrics, indicators, and tools utilized across environmental, economic, social, technical, business, and legislative dimensions.

A critical review methodology was adopted, analysing selected literature from the Scopus database. After rigorous screening, 17 relevant studies were subjected to detailed content analysis to identify prevalent methods and indicators. Key findings reveal that predominant methodologies employed include LCA, LCC, MCDM, C2C, and PBCI. Indicators commonly applied include embodied carbon, resource efficiency, cost-benefit analyses, social fairness, material separability, supply chain considerations, and policy compliance.

These findings highlight the fragmented but complementary nature of current approaches. To overcome the identified fragmentation and enhance practical circularity assessments, this study proposes an integrated methodological framework combining LCA, C2C, and PBCI (LCA-C2C-PBSCI). This framework merges environmental, technical, social, business, and legislative dimensions, enabling stakeholders to make informed, multidimensional decisions regarding building circularity. Practically, adopting this integrated approach can significantly streamline evaluations, promote consistent

practices, and facilitate broader implementation of circular principles in the construction industry.

Nevertheless, this study has limitations. The restriction of the literature search to the Scopus database potentially excludes relevant research indexed elsewhere. Additionally, the relatively small sample size may limit generalizability, and the broad scope adopted could overlook detailed nuances within specific dimensions. Future research directions should address these limitations by expanding database searches and validating the proposed integrated framework through empirical studies and practical case applications across various contexts. Developing standardized sets of indicators and tools is also recommended to facilitate comparability and consistency. Further exploration of underrepresented dimensions such as social and legislative aspects will enhance the holistic understanding and effectiveness of systemic circularity assessments.

6. ACKNOWLEDGEMENTS

The authors would like to thank the Faculty of Sciences, Engineering and Technology, of the University of Adelaide for financially supporting this study through the Early-Mid Career Research Grant (Project code 13137501).

CARBON FINANCING IN CONSTRUCTION: REVIEW OF BENEFITS AND BARRIERS

D.S.I. Wijayawardena[1] and K.A.T.O. Ranadewa[2]

ABSTRACT

The buildings and construction sector is responsible for 37% of global GHG emissions. Given the inefficacy of traditional methods in reducing GHG emissions, the adoption of sustainable strategies including low-carbon materials, energy-efficient practices, and the integration of renewable energy has become essential. Among these, Carbon Financing (CF) stands out as a mechanism that not only reduces emissions but also provides economic opportunities, making it highly attractive to investors. CF enables stakeholders to earn and trade carbon credits by reducing emissions allowing construction firms to monetise their environmental efforts. Hence this study aims to systematically review the benefits and barriers of CF for sustainable construction. The study conducted a systematic literature review on Carbon Financing (CF) in construction utilising the PRISMA framework. From an initial 126 articles, 91 articles were shortlisted for detailed analysis. Findings reveal a range of CF instruments categorised as primary products and derivatives, to manage carbon emissions and enhance market liquidity. Additionally, the study highlighted both the economic and environmental benefits of CF, including promoting green job creation, attracting investments in sustainable energy, and supporting biodiversity conservation. However, factors including lack of understanding, limited policy support, and a need for innovative CF products have been discovered as challenges faced in CF adoption. The study concluded that CF holds significant potential for transforming the construction sector into a more sustainable industry. This research contributes to the existing body of knowledge by providing a blueprint for integrating CF into construction practices while setting the stage for further research and practical application towards global sustainability goals.

Keywords: *Carbon Finance (CF); Carbon Market; Carbon Trading; Construction Industry.*

1. INTRODUCTION

Being the most resource-consuming industry (Feng et al., 2022), the construction industry is responsible for more than 40% of raw material consumption (Dixit et al., 2022) and over 30% of the world's energy consumption (Banawi & Bilec, 2014). This has led to the emission of significant amounts of harmful greenhouse gases (GHGs) into the environment. GHGs absorb and re-emit thermal radiation, thereby contributing to the warming of the planet's atmosphere. The principal GHGs include water vapor, carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), and ozone (Brander & Davis, 2012;

[1] Research Assistant, Department of Building Economics, University of Moratuwa, Sri Lanka, wijayawardenadsi.24@uom.lk
[2] Senior Lecturer, Department of Building Economics, University of Moratuwa, Sri Lanka, tharushar@uom.lk

Shirinbakhsh & Harvey, 2021). GHG emissions significantly contribute to climate change, threatening ecosystems, human health, and economic stability (Ling, 2021). To mitigate carbon emissions from the construction industry, various sustainable strategies can be employed. The adoption of low-carbon materials and energy-efficient practices (Zhang et al., 2024), integration of life cycle assessment (LCA), green supply chain management (GSCM), and the utilisation of renewable materials have emerged as viable approaches to address these issues. Among all these viable approaches carbon financing stands at the forefront of the global battle against carbon emissions. (Chien, 2024). CF, a branch of environmental finance, focuses on creating financial tools to achieve environmental goals and manage environmental risks (Li & Liu, 2011), and solve climate issues (Liu et al., 2015). It involves investment and financing activities within the low-carbon economy, aligned with the Kyoto Protocol of 1997 (Li & Liu, 2011) and the Paris Agreement of 2015 (Delbeke et al., 2019). One notable real-world example of carbon finance in practice is the Clean Development Mechanism (CDM) projects. CDM projects are sustaible initaitives focused on emission reduction (Mok et al., 2014). Later, the volume of emissions reduced is quantified and converted into Certified Emission Reductions (CERs), which can be traded on carbon markets to generate financial returns, becoming the (carbon) financing of the project. CF can influence carbon trading, enhance research and development efforts (Zhu et al., 2019), and encourage innovation of new materials with lower embodied carbon (Bamgbade et al., 2019).

CF can encourage industries to create green jobs (Wang et al., 2024) and it stimulates local economies to perform well (Chen & Wu, 2023). Additionally, due to CF's ability to influence low-carbon construction, it can reduce long-term operational costs of building making it a financially attractive sustainable practice (Topak et al., 2019). Carbon financial instruments can be effective in the construction industry, particularly when the upfront costs of adopting sustainable practices are significant (Liu et al., 2019). Despite its benefits, the adoption of CF face numerous challenges in construction industry (Wu et al., 2022). Lack of understanding on CF, insufficient knowledge about CF systems and shortage of experts in CF has made it less popular among the public (Liu et al., 2015). Additionally, existing policies, regulations, and legal frameworks not being robust enough to support CF, and lack of innovation in CF products (Parenteau & Cao, 2016) are two noteworthy challenges. The absence of a nationally unified carbon trading platform also poses problems in many countries (Wu et al., 2022). These obstacles highlight the complexity of implementing and adopting CF effectively in the construction industry.

Despite carbon financing's ability to empower sustainable construction, the integration of these financial mechanisms into the construction sector remains fragmented and underexplored. The existing literature offers a limited comprehensive analysis on the effectiveness of carbon financing in promoting sustainable construction practices. Recent literature, including Murali et al. (2024), investigates key enablers for integrating deconstruction and CF to enhance sustainable and resilient construction in the Industry 5.0 era. This complements Zhou and Li (2019), who explored the challenges and progress in implementing CF in construction, providing a foundation for understanding the obstacles faced. Oke et al. (2024) further contribute by identifying barriers to CF adoption and proposing practical solutions. Jiang et al. (2020) analyse the interplay between carbon trading, financing costs, and emission reduction strategies within the construction supply chain, shedding light on the financial mechanisms that influence emission reductions.

Even though there are studies on enablers, challenges, barriers, and solutions regarding the financial dynamics of carbon trading, there is a lack of an integrated framework that synthesises these various aspects. Each study, though valuable, tends to focus on specific dimensions without holistically addressing how these elements interact. For instance, studies such as Li (2020), Jiang et al. (2017), and Zhou and Li (2019) focuses on the Chinese construction industry, while research by Woo et al. (2020) and Eicker et al. (2020) primarily examine the US market. This regional focus creates a fragmented understanding, leaving a significant gap in understanding how carbon financing can be systematically applied to drive sustainability across the global construction industry. Therefore, this research aims to investigate the integration of CF into sustainable construction practices, with a specific focus on identifying the key benefits and barriers to its implementation within the construction industry. The systematic review will offer insights into the current state of knowledge, identify best practices, and propose recommendations for integrating carbon financing more effectively into the construction industry's sustainability strategies.

This paper is structured to provide a comprehensive exploration of the research topic. It begins with an introduction that outlines the background, significance, and aim of the study. The methodology section details the systematic approach employed to collect and analyse CF data. This is followed by a thorough systematic literature review, the paper reveals the CF instruments, key challenges, and benefits associated with the application of CF in the construction industry. Finally, the paper concludes with a summary of key findings, along with practical recommendations for future research and industry application.

2. RESEARCH METHODOLOGY

A literature review is a widely used technique in construction-related research to expand the body of knowledge on specific topics (Chen et al., 2022). To identify and select a relevant topic in academia, a systematic review of previous research is essential (Ayat et al.,2021). In this study, a scholarly journal article on CF in the construction sector was located using the Scopus search engine. Scopus was chosen for three main reasons: (1) it has been extensively used in construction review research (Osei-Kyei & Chan, 2015); (2) it is an effective tool for conducting literature reviews (Ghaleb et al., 2022); and (3) it is more accurate and reliable compared to other search engines like PubMed, Google Scholar, and Web of Science (Ahmad et al., 2021). The Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) framework was selected as the optimal methodology for this study after considering various systematic literature review methods. According to Shahruddin and Zairul (2020), PRISMA enhances the quality of evidence-based results and ensures transparency in the literature selection process. Moher et al. (2015) highlight that PRISMA's analytical and methodological approach is clear and straightforward. Further, Karunarathna et al. (2024) emphasise that a well-defined research topic is for a successful systematic review. The PRISMA framework explicitly incorporates the PICO (Populations, Interventions, Comparator, and Outcome) method for developing research questions of the study, as it facilitates literature reviews that address specific queries (Hosseini et al., 2024). Following Figure 1 presents the PRISMA flow diagram used for the study.

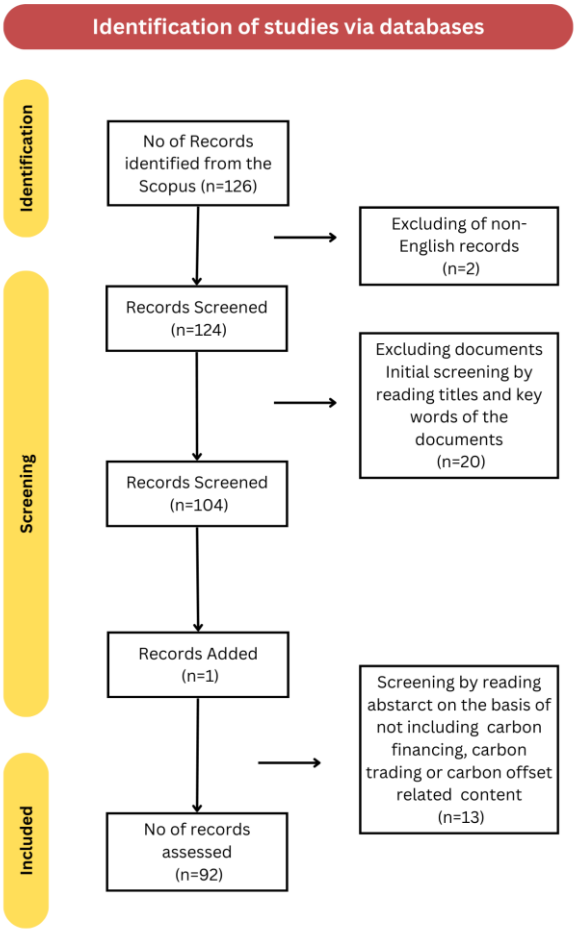

Figure 1: PRISMA flow diagram used for the study

The main search string used to retrieve bibliometric data related to the research area of concern was: ("carbon finance" OR "carbon financing" OR "carbon credit" OR "carbon trading" OR "carbon trade" OR "carbon offsetting" OR "carbon offset" OR "carbon accounting") AND ("construction industry" OR "building sector" OR "construction projects" OR "construction management"). Furthermore, more keywords and exclusion criteria have been used in the Scopus database to select relevant literature. Next, the screening process was performed by including journals, conference papers, and unpublished theses. Accordingly, 126 articles were selected from the search protocol. Due to language barriers, 2 non-English articles were excluded. Due to time and resource limitations, the search criteria were restricted to 'Article title, Abstract, Keywords.' From the remaining 124 papers, inclusion and exclusion criteria were applied to identify the most relevant papers and conduct a qualitative content analysis. The product-related papers, non-construction related papers, and papers that did not focus mainly on CF were excluded. As illustrated in Figure 1, 91 papers out of 124 were shortlisted. Papers have been reviewed using both content analysis and descriptive analysis. The content analysis was used to review the paper's contents thoroughly in broader themes such as (1) benefits of CF; (2) CF instruments; (3) challenges in CF; and (4) strategies to overcome the challenges. The research findings are presented in the two sections of the 'Findings and Discussion' section.

3. FINDINGS AND DISCUSSIONS

As GHG emissions continue to rise at alarming rates, the need for sustainable measures, including CF, is more critical than ever. Liu et al. (2019) explained that CF explores the financial implications of living in an environment where emissions of carbon dioxide and other GHGs carry a cost. Borghesi et al. (2015) describe carbon finance as encompassing activities that promote carbon emission reductions, such as investing in certified emission reductions (CERs) and carbon emissions trading. Liu et al. (2015) assert that carbon finance serves as an economic measure aimed at effectively addressing the climate problem. As noted by Su et al. (2023), CF includes cash flows from the sale of carbon credits, which represent the right to emit a certain amount of carbon dioxide. The UNHCR notes that CF is an innovative funding tool that places a financial value on carbon emissions, allowing companies to offset their emissions by purchasing credits from sustainable projects. Hence, CF is mostly integrated with trading carbon credits (Li & Liu, 2011; Zhou & Li, 2019).

Building upon this foundation, the ability to trade carbon credits and earn profits has become one of the main reasons for the popularity of CF as a business opportunity and investment among investors and businessmen (Su et al., 2023). The CF business primarily consists of two types. The first is the credit business, which focuses on the transformation of traditional industries through low-carbon upgrades, including CDM project investment and financing. The second is the intermediary business, which involves designing and developing carbon financial derivatives (Zhang & An, 2014). According to Labatt and White (2011), CF involves financial instruments and approaches that address climate issues through market-based solutions in a carbon-constrained world. Hence, these has become indispensable trading products in the CF market (Zhu et al., 2022). CF derivatives also known as CF instruments mainly include carbon futures, carbon options, and carbon swaps (Zhang & An, 2014; Sandor & Diperna, 2023; Liu & Li, 2024). Trading of CF derivatives occurs either on exchanges or over-the-counter (OTC) (Spilker & Nugent, 2022; Xu & Liu, 2023). These derivatives serve purposes such as hedging, carbon credit trading, and value discovery.

In light of these developments in the CF context, placing a monetary value on carbon emissions offers significant incentives and encouragement for construction firms to lower their emissions. Hence, CF has become an emerging area of focus within the construction industry. To further explore the role of CF in the construction industry, both content analysis and descriptive analysis were conducted to examine relevant literature and publication trends.

3.1 DESCRIPTIVE ANALYSIS

The publication trend of empirical studies conducted through the past years and the geographical distribution of related studies are insights through descriptive analysis.

3.1.1 Geographical Analysis

Understanding the geographical origins of research on CF within the construction industry offers valuable insights into global scholarly engagement and regional focus areas. As illustrated in Figure 2, the geographical distribution of CF-related publications demonstrates a growing global academic interest in applying CF principles to the built environment, underlining its rising relevance in achieving sector-wide sustainability goals.

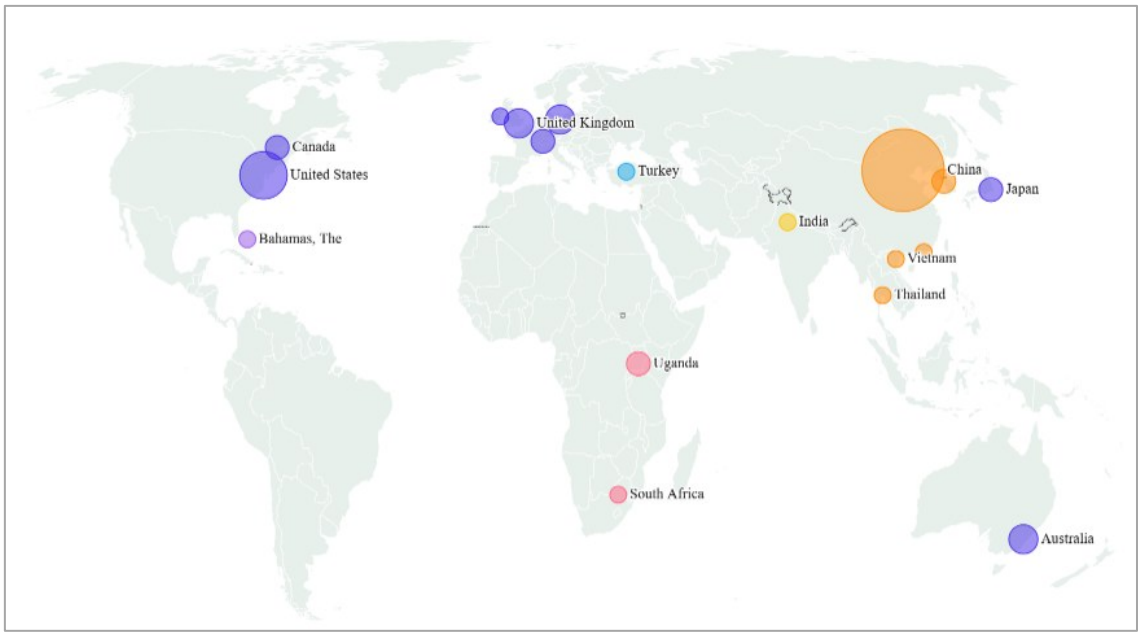

Figure 2: Geographical distribution of publications for CF of construction industry

The geographical distribution of publications illustrated in Figure 2 reveals significant disparities in research output on Carbon Financing (CF) within the construction industry across different regions. Countries like China and the United States emerge as leading contributors, reflecting their advanced commitments to climate action, regulatory frameworks supporting carbon markets, and institutional capacity to conduct large-scale research. China, in particular, dominates with 24 publications, likely driven by its national emissions trading scheme and increasing focus on green finance. In contrast, regions such as the EU and Europe, despite their progressive climate policies, show surprisingly lower publication counts, possibly due to data aggregation under broader European initiatives or journal indexing practices. Developed countries like Australia, Germany, the UK, and Canada exhibit moderate contributions, indicating a steady interest in integrating CF into sustainable construction practices. Meanwhile, developing nations including Uganda, India, South Africa, Vietnam, and Thailand demonstrate minimal scholarly activity. This limited engagement can be attributed to constraints such as resource scarcity, limited research infrastructure, and the prioritisation of socio-economic development over academic inquiry.

3.2 CONTENT ANALYSIS

The benefits and challenges associated with the implementation of carbon financing are thoroughly examined through the content analysis.

3.2.1 Benefits of CF

CF offers numerous benefits that significantly contribute to sustainable development and environmental protection. Table 1 presents the benefits of utilising CF.

Table 1: Benefits of utilising CF

Benefits	Sources
Global (Carbon) Emission Reductions	[1], [2], [3], [4], [5], [6],
Creation of Green Jobs	[4], [5]
Sustainable Energy Initiatives	[1], [2], [3], [4], [5], [6]
Biodiversity Protection	[7]
Climate Resilience	[1], [6]
Influence water quality trading	[8]
Cleaner Air and Health Benefits	[3]
Combatting Greenwashing	[9], [10]
Attract New Investments	[1]
Diversified Income for Communities	[1]
Economic Development for countries	[1]
Environmental Protection	[1], [5], [6]
Banks can enhance their capacity	[1]
International Cooperation	[1]

(1-Zhou & Li, 2019); (2- Yang & Luo, 2020); (3- Cai et al.,2016); (4- Wang et al., 2024); (5- Yu et al., 2021); (6- Firdaus & Arkananta, 2024); (7- Essl et al., 2018)

CF offers numerous benefits that significantly contribute to sustainable development and environmental protection. Among its primary advantages is the reduction of global carbon emissions, a critical step in combating climate change (Zhou & Li, 2019; Wang, 2021). The Olkaria II Unit 3 Geothermal Expansion Project in Kenya, the country's first CDM project to issue CERs, can be highlighted as a strong example of effective carbon financing (World Bank, n.d.). The project adds 276 gigawatts to the national grid while reducing 149,632 tonnes of carbon dioxide per year, making it a profitable project for both humans and the environment. In terms of climate resilience, CF plays a pivotal role by enhancing the capacity of communities to withstand environmental challenges such as floods and cyclones, thereby reducing vulnerability to climate-related disasters (Firdaus & Arkananta, 2024). Additionally, it creates green jobs, which are essential for promoting sustainable economic growth and providing employment opportunities within local communities (Yu et al., 2021). Moreover, CF supports sustainable energy initiatives, which not only reduce carbon footprints but also enhance energy security and resilience (Wang et al., 2024). Another key benefit is the enhancement of biodiversity protection, as CF backs projects that restore ecosystems and safeguard habitats for native species, addressing critical conservation needs (Essl et al., 2018). The majority of the benefits of CF also perform as a way to mitigate some of the environmental harms caused by the construction industry.

3.2.2 Challenges in CF

Despite the benefits the challenges faced while applying and utilising CF in the construction industry are also significant. Table 2 presents such challenges.

Table 2: Challenges encountered in utilising CF

Challenges	Sources
Global (Carbon) Emission Reductions	[1], [2], [3], [4], [5], [6],
Lack of understanding of CF	[1], [2]
Lack of knowledge on CF systems	[1], [5]
Lack of experts	[1], [5]
Lack of Transparency	[2], [3], [5]
Lack of innovation in carbon financial products.	[1], [2], [4], [5]
Lack of Universally recognised carbon market	[1], [3], [4], [5]
Lack of robustness in the existing policies and regulations,	[1], [5]
Lack of legal frameworks.	[1], [5]
Inaccuracies in Carbon Accounting	[2], [3], [5]
Difficulties in integration with Other Policies	[2], [3], [5]
Sectoral Fragmentation	[2], [4]
Price volatility	[2], [5]

(1-Liu et al., 2015; 2- Parenteau & Cao, 2016; 3- Wu et al., 2022; 4-Wang et al., 2019; 5- Lo, 2016)

A significant issue is the lack of understanding of CF (Liu et al., 2015), coupled with insufficient knowledge about CF systems and their operations (Lo, 2016). This knowledge gap extends to both financial institutions and enterprises, limiting their ability to fully engage in carbon financing initiatives (Liu et al., 2015). Despite the significant knowledge on CF in many Western countries, some nations, including China, have a more limited understanding of establishing and developing a comprehensive carbon financial system even by 2019 (Zhou & Li, 2019). Furthermore, the shortage of experts in CF (Lo, 2016), has reduced its popularity among the public and within industries. The inadequacy of existing policies, regulations, and legal frameworks further exacerbates the challenges faced by CF, as these frameworks are often not robust enough to support CF adequately (Zhou & Li, 2019). Chinese literature including Zhou and Li (2019) highlighted the absence of a nationally unified carbon trading platform as another significant hurdle. For the construction sector, a unified platform could streamline the process of acquiring carbon credits, making it easier for companies to offset emissions and invest in greener technologies.

3.2.3 Final Framework

Based on the findings of the study, a comprehensive final framework has been developed, encapsulating the key insights and outcomes derived from the research. This framework serves as a visual synthesis integrating the major findings, highlighting both the benefits and challenges of carbon financing, along with the classification of its financial instruments. As illustrated in Figure 3 the framework provides a structured representation of how carbon finance operates, offering a clear and concise overview of its benefits, limitations, and strategic mechanisms.

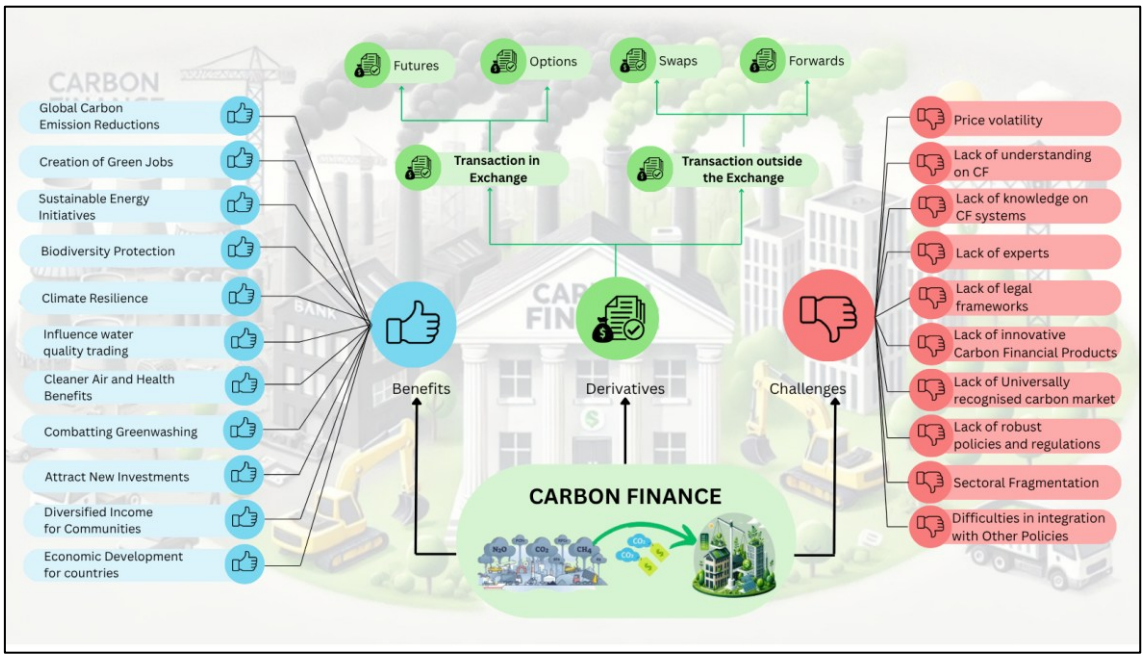

Figure 3: Final framework

Figure 3 presents a comprehensive visual framework of Carbon Finance, organising its key components into three interconnected segments: derivatives, benefits, and challenges. At the centre lies the core concept of "Carbon Finance," symbolised by a gradient illustration that contrasts pollution from industrial. Furthermore, the top section categorises carbon finance derivatives into two transaction types: those occurring outside the exchange (swaps and forwards) and those within exchange markets (options and futures), clearly showing the structural division in financial instruments. On the right, the benefits of carbon finance are listed within a green bubble, emphasising environmental, economic, and institutional gains such as emission reductions, creation of green jobs, sustainable energy initiatives, and enhanced international cooperation. Opposite this, the left section highlights the challenges, including a lack of expertise, transparency, legal frameworks, and policy integration, as well as issues like price volatility and sectoral fragmentation. Together, the image effectively illustrates how carbon finance operates at the intersection of environmental goals, market mechanisms, and systemic barriers, offering a clear and structured understanding of its multifaceted impact.

4. CONCLUSION AND RECOMMENDATIONS

CF is an emerging and largely underexplored area within the context of sustainable construction, offering innovative financial mechanisms that could significantly reduce the environmental footprint of the construction industry. Despite its immense promise, CF remains a hardly touched concept in the construction sector. Hence, this study has explored the critical role of CF in sustainable construction by introducing financial solutions to reduce GHG emissions. This paper contributes to the body of knowledge by providing an in-depth exploration of CF within the construction industry. It offers a comprehensive definition of CF specific to construction while emphasising the CF instruments that can be utilised. The paper also examines the geographical distribution of CF research, revealing the disparity between developed and developing countries.

Additionally, the paper discusses the challenges and benefits of CF, while highlighting its potential to drive sustainable construction practices when applied effectively.

Building on these insights, this study serves as a blueprint for integrating CF into construction practices. By addressing the current challenges and implementing the presented recommendations, the construction industry can move towards a more sustainable future where CF becomes an essential component of its sustainability strategy. This groundwork sets the stage for CF to be a cornerstone of sustainable construction. To achieve this, the study recommends that industry practitioners take several key actions. First, stakeholders, including policymakers, construction firms, and financial institutions should be educated about the benefits, markets, and systems of CF through targeted training programs and workshops. Second, robust policies and regulations must be developed to support CF initiatives, including a clear and universal set of guidelines. Third, utilisation of CF instruments should be encouraged, and new derivatives should be developed to cater to the evolving needs of the construction market. Finally, the creation of a nationally or regionally unified and recognised carbon trading platform is essential to streamline processes and enhance transparency.

Future research could focus on developing sector-specific carbon finance models tailored to the construction industry's unique emissions profile. Additionally, exploring digital tools, including blockchain to enhance transparency and accuracy in carbon accounting is vital. Finally, studies should assess stakeholder knowledge gaps and propose targeted capacity-building initiatives to support the adoption of carbon finance within the sector. Research should continue to explore the interplay between CF and other sustainability initiatives to create a holistic approach to reducing the environmental impact of the construction industry.

5. ACKNOWLEDGEMENT

The authors greatly acknowledge the financial support provided by the Senate Research Committee of the University of Moratuwa under the Grant SRC/LT/2024/12.

CAUSES, DETECTION AND REMEDIATION OF WATER-INDUCED BUILDING DEFECTS: A SYSTEMATIC REVIEW

Argaw Gurmu[1], Dulani Denipitiya[2] and Pabasara Upalakshi Wijeratne[3]

ABSTRACT

Water ingress in buildings can considerably impact the building and its occupants by compromising structural integrity, health, safety, and financial stability. While existing research has identified common defects associated with water seepage, a comprehensive framework for systematically documenting these issues and their corresponding solutions is currently needed. This study aims to comprehensively review the means of water ingress, its root causes, associated defects, detection methods, and remediation techniques, using the Preferred Reporting Items for Systematic Reviews and Meta-Analysis guidelines. A comprehensive search was conducted on articles related to water ingress-related building defects in the Scopus and Web of Science databases. Content and thematic analysis methods were applied to analyze 66 publications. The study identified seven vulnerable building components: exterior and interior walls, facades, roofs, basements, wet areas, and plumbing systems. It was found that cracks, faulty joints, defective fittings, and inadequate waterproofing lead to water ingress, causing structural, aesthetic, and functional damage. Further, detection methods ranging from visual inspections to advanced technologies like thermography and unmanned aerial vehicles (UAVs) were explored and various remedial actions including repairing, replacing, or reconstructing affected elements were suggested. The framework presented in this study provides design and construction professionals with proactive strategies for detecting and remedying water-related defects, offering practical guidelines for informed decision-making to effectively manage building defects linked to water ingress.

Keywords: *Building Defects; Causes, Diagnosis; Maintenance; Systematic Review; Water Ingress.*

1. INTRODUCTION

In the construction industry, one of the main concerns post-constructions is the manifestation of building defects. This issue carries economic implications (Talib & Sulieman, 2020), affects the builders' reputation (Gurmu et al., 2021) and compromises building quality (Jonsson & Gunnelin, 2019). In Australia, building defects cost around $2.5 billion annually with rectification accounting for 75% of the total cost (The Centre for International Economics, 2021). Defects occur due to poor workmanship, non-

adherence to building design and standards, low-quality materials, and inadequate maintenance (Chong & Low, 2006). Notably, water-related defects are the most prevalent (Chew & De Silva, 2003b). In Australia, 42% of defects are related to water leaks with exterior water penetration and plumbing faults accounting for 40% and 22%, respectively (PICA, 2021).

Water ingress continues to pose significant structural and economic risks (Chew & De Silva, 2002), and contributes to energy loss (Kirimtat & Krejcar, 2018). Rectification costs for water-related defects are 42% in residential buildings and 31% in commercial buildings (The Centre for International Economics, 2021). Additionally, moisture intrusion promotes mould growth, creating unhealthy living spaces (Coulburn & Miller, 2022). Often latent in nature, these defects appear over time and may be overlooked (Chong & Low, 2006), highlighting the need for better understanding and prevention of water ingress.

The existing literature on building defects and water ingress tends to focus broadly on building defects, with limited emphasis on water or plumbing-related issues (Gurmu & Mudiyanselage, 2023). While previous studies have explored the causes and manifestations of this phenomenon in different building areas (Chew & De Silva, 2003a) as well as methods for detecting water or moisture ingress (De Filippo et al., 2023), the literature remains fragmented. Additionally, existing remediation discussions predominantly address defects in a general context (Sandanayake et al., 2022), lacking a comprehensive framework that integrates the causes, resulting defects and remedial strategies for water ingress. Thus, the research gap identified here is twofold: first, there is a need for focused studies on water and plumbing defects; second, a holistic framework linking water ingress causes with defects and remediation strategies is missing. Addressing these gaps will enhance understanding and inform practical strategies for addressing water-related defects. This study will investigate water ingress and develop a framework linking causes, defects, identification techniques, and remediation strategies.

2. LITERATURE REVIEW

Several studies have explored building defects and their causes. Sandanayake et al. (2022) reviewed residential building defects in Victoria, Australia, and found that poor workmanship was the leading cause, responsible for 90% of rectification costs, with waterproofing and water penetration defects having the highest cost implications. However, their study was limited to residential buildings. Talib and Suleiman (2020) categorized defects into latent and non-latent types, noting that dampness from water ingress was the most common latent defect, also contributing to other non-latent defects.

Recognizing water ingress as a major contributor to building defects, several studies have examined water-related issues. Chew et. al (2004) analyzed defects in wet areas in 56 non-residential high-rise buildings in Singapore, identifying 14 common defects, nine of which were linked to water penetration or moisture. These included water leakage, staining, paint defects, concrete spalling, tile debonding, water ponding, and corrosion, with construction deficiencies being the primary cause (43%). Similarly, Chew & De Silva (2003b) found that ceiling leaks accounted for 36% of defects in residential high-rise buildings, leading to fungi growth and paint deterioration. However, these studies predominantly focus only on wet areas of a building. Later research also highlights

internal and ceiling leakages as major defects caused mainly by construction issues (Gurmu et. al., 2025).

Studies on basement water seepage have identified plumbing leaks, poor waterproofing, and groundwater changes as key contributors to below-ground defects, which can compromise structural integrity (Chew & De Silva, 2003a). Gurmu and Mudiyanselage (2023) reviewed residential plumbing system anomalies, identifying leakage, clogging, corrosion, damaged pipes, faulty equipment, and poor installation as common causes, along with diagnostic methods for defect identification. However, these studies focus on specific areas - wet zones, basements, or plumbing - rather than providing a comprehensive review of water-related defects across an entire building.

Studies on inspection methods include Kot et al. (2016), who applied electromagnetic waves to detect water infiltration in concrete flat roofs, enabling early identification of moisture content to prevent critical defects. De Filippo et al. (2023) explored the use of UAVs with AI algorithms for defect detection, although their research focused only on identification without addressing causes or remediation. Chong and Low (2006) examined design-related defects in 74 buildings, attributing failures like plaster cracks, staining, and paint peeling to weather, occupant impacts, load, and moisture from wet areas. They offered strategies on material use and water leakage prevention. Ghani et al. (2023) emphasized the importance of planned maintenance and regular visual inspections to reduce the occurrence and impacts of building defects, including water ingress. Accordingly, the existing literature highlights the significant impact of water ingress-related defects in buildings. However, a comprehensive analysis of their causes, implications, and remediation has not been thoroughly explored. Therefore, further research is necessary to gain a holistic understanding of these defects.

3. RESEARCH METHODOLOGY

This study aimed to comprehensively review existing literature on water ingress in buildings, focusing on the causes and associated defects. A stand-alone review approach was adopted, which is effective for summarizing prior research and providing valuable insights (Templier & Paré, 2015). The research utilized a systematic literature review (SLR), a structured and transparent method that enhances the quality, replicability, reliability, and validity of findings (Xiao & Watson, 2019). Following the SLR guidelines outlined in Xiao and Watson (2019), the study defined its scope, searched and screened relevant literature, extracted and analyzed data, and reported the findings. It focused on building defects and water ingress, using Scopus and Web of Science (WoS) databases, which are widely recognized for comprehensive coverage (Sandanayake et al., 2022). A rigorous review protocol was established, following the Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA) framework as shown in Figure 1.

The literature search keywords were based on research themes and included commonly used synonyms. The search string for Scopus was TITLE-ABS-KEY ("building*") AND TITLE-ABS-KEY ("defect*") AND TITLE-ABS-KEY ("water") OR TITLE-ABS-KEY ("moisture") AND TITLE-ABS-KEY ("ingress") OR TITLE-ABS-KEY ("leak*") while a similar string was used for WoS as ("building*" AND "defect*" AND ("water" OR "moisture") AND ("ingress" OR "leak*")). The asterisk was used to include all possible variations of relevant search terms.

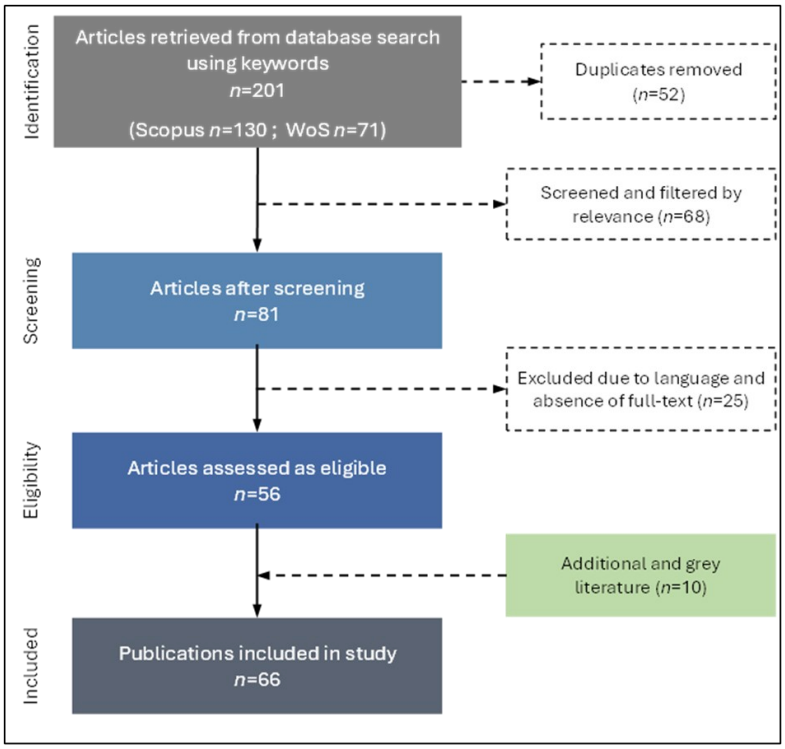

Figure 1: Article screening and eligibility assessment protocol – PRISMA Flowchart

The search focused on scientific publications, including journal papers, conference papers, books, and book chapters. Scopus yielded 130 records, and Web of Science (WoS) provided 71, totalling 201 records as of October 2023. After removing 52 duplicates, titles and abstracts were screened, excluding 68 irrelevant publications. Further, 25 non-English or unavailable full-text papers were removed, leaving 56 eligible for analysis. Additionally, 10 grey literature sources from government and private organizations were included. Ultimately, 66 publications were reviewed, comprising 42 journal articles, 18 conference papers, 1 book section, and 5 reports. The research used content analysis to organize and categorize articles, identifying patterns related to building defects caused by water ingress (Bengtsson, 2016). The literature findings were categorized into five main areas: (1) means of water ingress into buildings, (2) causes of water ingress and associated defects, (3) defects caused by water ingress, (4) methods of detecting water ingress, and (5) remediation techniques.

The research employed thematic analysis to synthesize the data and identify emerging themes (Clarke & Braun, 2017). A defect and cause table was created in Microsoft Excel to analyze the causes, related defects, and remediation for each component, while detection methods were analyzed separately.

4. RESULTS AND DISCUSSIONS

The review of articles identified key themes related to water ingress in buildings, including the most vulnerable building components, associated defects, detection methods, and remediation techniques. The findings highlight the vulnerabilities of these components and discuss the multifaceted nature of water ingress, offering potential remediation strategies for the construction industry. Figure 2 presents the framework

developed based on the SLR of existing literature. Detailed discussions of the framework are provided in the subsequent sub-sections.

Figure 2: Framework for water ingress into buildings

4.1 Means of Water Ingress

Water ingress in buildings manifests in different forms, affecting structural integrity and indoor air quality. Sahi et al. (2022) categorize water ingress into three types: water penetration/leakage, moisture/dampness, and airborne particles (aerosol). The causes and defects related to these types vary depending on the building component. Studies have identified seven key vulnerable areas where water ingress occurs, including exterior and interior walls, basements, wet areas (ceilings and floors), roofs, building façades, and plumbing systems.

Exterior walls act as a barrier between indoor and outdoor environments, making them vulnerable to water infiltration, especially when construction deficiencies and deteriorating materials create pathways for moisture to enter (Talib & Sulieman, 2021). Similarly, building façades, which include cladding, windows, doors, and balconies, are crucial in preventing water ingress. Inadequate weatherproofing and faulty installation of façade components can lead to water infiltration and allow moisture and airborne particles

to enter (Jonsson & Gunnelin, 2019). Interior walls, designed as partitions, can retain moisture if leaks or cracks compromise the building envelope (Yu et al., 2023).

The most common areas in which water ingress in buildings are wet areas, including bathroom, kitchen, and utility room floors and ceilings, due to their frequent exposure to moisture (Chew, 2005). Water penetration in these areas is often linked to structural damage and mould growth (Chong & Low, 2006). Roofs, another key defence against environmental elements, are also prone to water infiltration, leading to leaks and moisture issues (Kot et al., 2016). Basements are at high risk due to groundwater seepage and construction defects, which can severely affect structural integrity (Chew & De Silva, 2003a). The plumbing system, including water supply, drainage, and water tanks, is a major source of water ingress, with leaking pipes and poor drainage contributing to water damage and indoor air quality problems (Gurmu & Mudiyanselage, 2023). The next section will explore the defects and causes linked to these building components.

4.2 DEFECTS THAT CAUSE WATER INGRESS INTO BUILDINGS

Exterior walls often give way to water penetration due to structural defects such as cracks or gaps, faulty building joints, and porosity in the materials used for construction. These defects are commonly induced by structural movements, poor construction practices and material use, while inadequate waterproofing further encourages greater water absorption (Talib & Sulieman, 2021). Defects identified in building facades include anomalies in balconies, windows and door seals which create air and moisture gaps (Crean, 2017). These defects are often attributed to environmental exposure such as high winds, UV radiation and rain, and defective installation and materials (Cladding Safety Victoria, 2023). Similar to exterior walls, interior walls are also susceptible to cracks resulting from structural and construction deficiencies. Additionally, improperly sealed gaps where the wall is penetrated by plumbing or other fixtures highlight the need for meticulous installation practices (Singh et al., 2011). Furthermore, high humidity and condensation due to restricted airflow contribute to moisture retention in indoor spaces which have been linked to the deterioration of wall finishes (Felipo & Charpin, 2022).

While its characterisation implies the presence of water, anomalies such as water leakage from faulty pipes and cracks in the floor or wall joints due to poor workmanship and excessive moisture absorption pose added risks in wet areas (Sahi et al., 2022). Additionally, design defects leading to water ponding, along with inadequate drainage and waterproofing issues, highlight the importance of thorough inspection and repair protocols (Chew & De Silva, 2003b).

The roof presents susceptibility to water ingress through the manifestation of cracks and material deterioration due to high exposure to environmental conditions and construction deficiencies. Inadequate attention to specifications also causes defects in construction joints and drainage resulting in water penetration into the building (Pamera & Gurmu, 2020).

Cracks in the foundation often induced by structural movements or poor construction practices and faulty joints serve as conduits for water and moisture penetration in basements. Additionally, the lack of good airflow in these spaces intensifies moisture retention (Chew & De Silva, 2003a). Similarly, there are several common defects associated with water ingress within the plumbing system. The defects associated with water supply are water leakage due to faulty pipes or fixtures, corrosion of pipes and

overflowing tanks (Gurmu & Mudiyanselage, 2023). Pipe leakage was identified as the most commonly occurring defect. The defects related to sanitary drainage include defective water trap seals and sewer backflow resulting from defective installation, which has been linked to the dispersion of contaminated aerosolized particles and the transmission of pathogens, with severe health implications (VBA, 2023). Additionally, the incorrect discharge of stormwater from the roof and defects in swimming pool structures caused by defective design and installation are also identified as contributing to water ingress.

The defects that encourage water ingress in buildings are often physically evident; however, they may not always be visually distinct. Overall, the defects discussed above were identified as commonly associated with issues relating to inadequate design, low-quality material use, poor workmanship and lack of regular maintenance of buildings. The origin of these defects could further be linked to the designers, contractors, material suppliers and maintenance contractors (Chong & Low, 2006). However, similar to the findings by Chew (2005) and Chew and de Silva (2002), most causes were attributed to the construction stage, particularly deficiencies or non-adherence to construction standards and attention to detail. Nevertheless, understanding the root causes of these defects is necessary for implementing effective remediation strategies.

4.3 DEFECTS CAUSED BY WATER INGRESS

Water ingress, caused by defects in building structures, leads to additional issues such as structural, aesthetic, and functional defects. Structural defects are defined as issues that compromise the structural integrity and stability of a building. Water and moisture in buildings have been identified as causing deterioration of building materials and corrosion of structural components leading to the weakening of the overall structure (Singh et al., 2010). Aesthetic defects refer to damages primarily affecting the appearance of the building. Water ingress not immediately visible to the occupants is often first visible through defects in the paint/plaster such as peeling, blistering or flaking on walls and ceilings, discolouration of surfaces and increasing efflorescence. These defects occur as a result of water seepage and excessive moisture absorption on surfaces (particularly those in proximity to wet areas), which also lack sufficient waterproofing (Chew & De Silva, 2002). While they may not directly compromise the structural integrity of a building, they significantly impact its visual appeal and are typically common visual indicators of water damage.

Functional defects impact the usability of the building, affecting the comfort, convenience as well as health and wellbeing of its occupants. Water ingress has been associated with electrical system malfunctions and plumbing defects caused by corroding pipes which are both functional and safety hazards (Law et al., 2021). However, it is more commonly associated with the growth of toxic mould and algae on surfaces exposed to moisture and dampness which is a significant health hazard in most affected buildings (Felipo & Charpin, 2022). Water ingress in indoor spaces, combined with low ventilation can create a suitable environment for fungal growth and once established, could affect material with low moisture content (Talib & Sulieman, 2020). This has been linked to respiratory issues and allergies among exposure to other health risks, leading to ‘sick buildings’ (Singh et al., 2010). Additionally, the presence of water could also encourage insect infestations and the breeding of mosquitos (Singh et al., 2010). These defects highlight the significance of this issue and the immediate need to address them. Thus, it is important

to identify these defects such that the root cause or origin can be addressed to ensure the functionality and structural integrity of the building. The following section discussed methods of detecting water ingress and associated defects.

4.4 DETECTION METHODS

The literature identifies various methods for detecting water ingress or damage, with a focus on non-destructive techniques. These methods differ in the technology used but all aim to identify affected areas and determine the underlying causes of water-related issues. The most traditional method to detect water ingress is through regular visual inspection (Bortolini & Forcada, 2018). This refers to visually examining different components of a building for signs of water leaks, staining, dampness, condensation, mould or algae growth and corrosion (Wahab & Hamid, 2011). It also serves as the initial step in diagnosing potential defects, to guide further investigation or testing, if needed. However, effective inspection and results rely on the expertise and experience of the inspector (Gurmu & Mudiyanselage, 2023). Other traditional testing methods include the use of moisture meters and electrical resistance or conductivity tests, which are both low-cost strategies for measuring moisture in building materials (Phillipson et al., 2007).

Thermography and microwave technology are non-destructive methods that can be used to detect water ingress and related defects that are not visually evident. Thermography detects variations in surface temperature based on thermal properties, which can reveal underlying dampness or water within the structure (Pamera & Gurmu, 2020). Similarly, microwave technology allows areas of leakage due to cracks in concrete structures (Kot et al., 2016). This could be a more effective method if used together with thermography, where the water-ingress areas can be more easily detected due to the specific temperature distribution caused by microwave heating (Barreira et al., 2013). However, the level of moisture content cannot be evaluated with these methods (Phillipson et al., 2007). More recent innovations include the use of UAVs and robotic technology to diagnose defects, particularly on building facades. These methods can provide 3D visual and thermal data and locate points of air or moisture leakage more accurately, thereby, reducing operational costs and safety risks (De Filippo et al., 2023). These methods are most suitable for inspection of high-rise buildings.

In addition to visual inspection, defects in the plumbing system can be diagnosed using specialized equipment and testing methods. Water leaks and faulty pipes could be identified using hydrostatic pressure tests. Additionally, infrared cameras combined with listening devices such as leak detectors and leak loggers can be used to isolate points of ingress, particularly in inaccessible areas, such as underground piping and within walls and slabs (Gurmu & Mudiyanselage, 2023). Water trap seals within the sanitary drainage system have been previously tested using air pressure transient simulation in building drainage and vent systems. This operates similarly to a sonar system, reflecting air pressure waves off drainage boundaries, and revealing defective seals (Swaffield, 2005). The detection of defective water trap seals can be significant in preventing cross-contamination and the spread of infectious diseases.

4.5 REMEDIATION OF WATER-RELATED DEFECTS

The above sections discussed the causes and defects of water ingress in buildings, along with methods for detecting and addressing them. The required remedial actions such as repair, replacement, or management depend on the stage at which the defects are

diagnosed. Nevertheless, the foremost step would be to control water ingress at the source or remove the source (Singh et al., 2011). To do this, the results suggest that the most common method is to seal sites of infiltration or repair defects that could lead to water ingress in the future. This includes repair or replacement of defective elements and substandard material (Chong & Low, 2006) and appropriate application of waterproof coatings or sealant. Waterproofing is a key step in the construction process which limits moisture levels on building surfaces, preventing water-related aesthetic and structural damage. It also protects against the growth of toxic moulds. However, if there is existing evidence of dampness or mould, immediate remediation is necessary to minimize health risks to the occupants. The most effective strategy in this instance is cleaning or treating affected surfaces by chemical means and improving ventilation and airflow (Singh et al., 2010). Humidity control and maintenance of HVAC systems could further address issues and defects associated with condensation and moisture retention (Wang & Yin, 2019).

The defects previously discussed also revealed design and construction-related causes due to possible non-compliance with standards and guidelines. Some of these defects may require design improvements or reconstruction of the related elements to rectify the damages. This highlights that many building defects are not merely symptoms of isolated workmanship issues but are indicative of more systemic shortcomings in design decision-making, quality assurance practices, and regulatory enforcement. The identified defects, such as water ingress, concrete cracking, and joint failures, signal a disconnect between design intentions and construction execution. These issues may also reflect a lack of robust feedback mechanisms from post-construction performance data into future design and specification standards. Thus, the findings from this SLR could inform a design-feedback framework, where recurrent defects become catalysts for revising design protocols, detailing practices, and material selections, thereby preventing recurrence in future projects.

Additionally, remediation must be undertaken following the appropriate design and construction specifications (Chong & Low, 2006). Furthermore, building defect investigations often take place following signs of damage that might hinder the functionality of the building, requiring extensive repair which is both time-consuming and costly. This can be avoided by regular inspection and appropriate maintenance of the building (Talib & Sulieman, 2021). Maintenance that is unplanned and occurs following defect diagnosis to rectify the defect and its causes is referred to as corrective maintenance. Conversely, preventive maintenance involves planned strategies to minimize the materialisation of such defects. Of these, preventive maintenance is identified as the most suitable and effective strategy to ensure the long-term structural and functional integrity of the building (Ghani et al., 2023). Thus, it can be noted that preventive maintenance of buildings together with good construction practices could limit water-related defects and the need for defect remediation.

4.6 IMPLICATIONS OF THE STUDY

This research enhances the theoretical understanding of water ingress in buildings by systematically examining its causes, related defects, identification methods, and remediation strategies. It proposes a comprehensive framework that connects these elements, offering a theoretical model for addressing this complex issue and forming a foundation for future research in building maintenance and pathology. By integrating

knowledge from engineering, construction management, and materials science, the study strengthens the interdisciplinary foundation related to building defects and water ingress.

The research also offers valuable insights for architects, engineers, and construction professionals by identifying common causes and defects associated with water ingress. The findings support improvements in building design, material selection, and construction techniques to mitigate water intrusion risks. The framework can improve maintenance and inspection processes, enabling early detection and resolution of water ingress issues, thereby extending the building's lifespan. By linking specific causes to effective remediation strategies, the study provides practical guidance for developing cost-effective repair plans to prevent structural and aesthetic damage.

5. CONCLUSION

Water ingress in buildings poses significant challenges to the construction industry, impacting structural integrity, indoor environmental quality, and occupant well-being. This review comprehensively analyzed defects linked to water ingress, highlighting causes, resultant defects, and remediation strategies. Key vulnerable components identified include exterior and interior walls, façades, roofs, basements, wet areas, and plumbing systems. Defects such as cracks, faulty joints, material deterioration, and inadequate waterproofing contribute to water penetration and typically arise from issues in design, workmanship, materials and maintenance. Water ingress leads to structural, aesthetic, and functional problems, affecting building stability and appearance. Detection methods range from visual inspections to technologies like thermography and UAVs. Remediation involves sealing, repairing, replacing, or redesigning affected elements, with preventive maintenance being essential to prevent future defects and maintain a healthy environment. The study emphasizes the need for better design and construction practices and greater awareness of the impacts of poor workmanship and maintenance. Findings can guide contractors, architects, and engineers to prevent water ingress and support building owners and managers in developing proactive maintenance strategies to reduce costs and minimize occupant disruption. Although the study offers a framework for understanding water ingress causes, defects, and remediation, it relies on existing research and may not capture all defects or regional variations. Future research could examine specific building components in greater depth and contribute to improved construction standards and diagnostic tools.

CLIENT SATISFACTION MODEL FOR LEAN IMPLEMENTED CONSTRUCTION SMES: A REVIEW

K.G.P.N. Munasingha[1], K.A.T.O. Ranadewa[2] and M.R.D.P. Wijerathna[3]

ABSTRACT

Client satisfaction is a critical determinant of success in the construction industry, particularly for small and medium-sized enterprises (SMEs) that have implemented lean principles. Despite the recognised benefits of lean construction, many SMEs continue to struggle with achieving high levels of client satisfaction. While existing studies primarily explore the advantages and challenges of Lean implementation, there is a lack of research that specifically investigates the underlying causes of less client satisfaction in Lean implemented construction SMEs. Therefore, this study aims to bridge this gap by developing a conceptual framework for a client satisfaction model tailored to lean implemented construction SMEs. A literature review was conducted to examine the key factors affecting client satisfaction in lean implemented construction SMEs. The review analysed existing studies on lean construction, client satisfaction, and SME-specific challenges to identify critical themes. The data was synthesised to develop a framework that integrates lean principles, benefits, barriers, factors influencing client satisfaction, and reasons for failing to meet client expectations. The findings highlight that perceived quality, customer satisfaction, and customer loyalty are interrelated, with higher satisfaction leading to increased client retention and improved financial performance. Additionally, the study identifies key barriers that hinder client satisfaction in lean implemented SMEs, including ineffective communication, resistance to change, and inadequate understanding of lean principles. This study contributes to both theory and practice by offering a structured framework to enhance client satisfaction in lean implemented SMEs. It provides SMEs with strategic insights to improve lean adoption while recommending future research directions to empirically validate the proposed framework through case studies and stakeholder engagement.

Keywords: *Client Satisfaction; Construction; Lean; SMEs.*

1. INTRODUCTION

Construction SMEs play a vital role in the economy by creating jobs, contributing to economic growth and stability, and remaining one step below large construction companies (Ranadewa et al., 2018; Palacios-Manzano et al., 2024). Globally, SMEs are contributing significantly to innovation, economic growth, poverty reduction and supporting job opportunities and large-scale enterprises (Ismail et al., 2023). Often

[1] Undergraduate, Department of Building Economics, University of Moratuwa, Sri Lanka, poornimanishadi2000@gmail.com
[2] Senior Lecturer, Department of Building Economics, University of Moratuwa, Sri Lanka, tharushar@uom.lk
[3] Lecturer, Department of Building Economics, University of Moratuwa, Sri Lanka, dewminir@uom.lk

construction SMEs are responsible for residential, commercial and infrastructure developments due to the rising demand (Motsetse, 2015). As demand for affordable housing increases, while raw materials become scarcer, medium construction firms need to adopt creative circular economy practices (Zuofa et al., 2023). These practices will help them build sustainably and grow their businesses, providing a strong reason to embrace circular economy principles in their construction processes (John et al., 2023).

Even though SMEs were able to gain more benefits than micro-sized firms due to the availability of required basic capacities, most SMEs are still unfamiliar with the lean concept (Ranadewa et al., 2015). According to Balkhy et al. (2021), the performance and productivity of a company can be achieved through a lean implementation to SMEs in the construction sector. Lean offers several intrinsic direct advantages that improve an organization's capacity to compete successfully by increasing operational effectiveness and efficiency. Worldwide construction industries have adopted lean construction and have reaped its benefits (Dehdasht et al., 2020).

According to Demirkesen and Bayhan, (2022), the most important benefit from LC (lean construction) will be client satisfaction when implementing lean construction under customer focus. Lean principles in the construction industry can minimize and eliminate non-value adding activities, increasing value for the client (Maradzano et al., 2019). Even though many construction companies across the globe have embraced lean principles, the achievement of client satisfaction for many of the construction firms is still a dream (Bayhan et al., 2019). Therefore, construction industry needs to understand the essential factors for enhancing lean implementation that would eventually improve client satisfaction. However, due to the fact that lean principles have not been implemented to the fullest, some of the SMEs have failed to achieve their objectives (Yusup et al., 2015) and could not achieve the expected client satisfaction level.

Most studies have been done to address the barriers to lean implementation and have developed models for those causes. Durdyev et al. (2018) have developed a client satisfaction model: a PLS-SEM approach to investigate the service quality on construction client satisfaction. In the local context, De Silva et al. (2023) have done a fuzzy TOPSIS analysis for implementing Lean Six Sigma in SMEs in the construction industry.

Despite that, there is lack of studies that specifically address the causes for lack of client satisfaction in lean implemented construction SMEs, as the problem remains the same. Therefore, this research aims to develop a framework for a client satisfaction model in lean implemented construction SMEs. The structure of the paper is as follows: It begins with an outline of the methodological approach. This is followed by the presentation of research findings, derived from an extensive literature review. Finally, the paper concludes with a summary and suggestions for future research.

2. METHODOLOGY

The method adopted is a literature review of the LC at SMEs in the construction industry. The literature review is a comprehensive and reproducible method for identifying, evaluating, and synthesising the existing body of recorded knowledge produced by researchers, scholars, and practitioners (Chen, 2017; Pollock & Berge, 2018). Literature reviews are essential in generating evidence from existing studies and for their ability to

create new knowledge by compiling the existing works, which is essential for directing new research (Cobo et al., 2011).

The review covers the literature published in the last 15 years between 2010 and 2025 (March), a period in which both the lean and SMEs research domains have visibly matured and attracted significant attention from researchers and practitioners. Figure 1 describes the research process of this study.

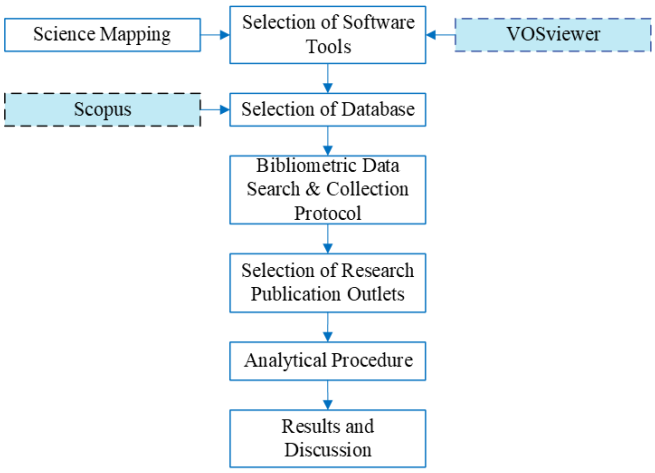

Figure 1: Research Methodology

In the first step of the literature review, the following main keywords were searched in the titles, abstracts and (or) keywords of publications in three search rounds: {("Lean" OR "Lean construction" OR "Lean principles" OR "Lean management" OR "Lean implementation" OR "Lean tools") AND ("small and medium-sized enterprises" OR "SMEs" OR "Construction SMEs") AND ("construction industry" OR "construction sector" OR "building industry" OR "construction projects" OR "construction" OR "building sector")}. Articles were identified after the exclusion of non-peer reviewed publications, articles out of the construction research domain, and articles that do not actually discuss or do not mainly focus on Lean and construction at SMEs in the construction industry even though they contain those keywords in their titles, abstracts, and (or) keywords.

3. FINDINGS

3.1 LEAN IMPLEMENTED CONSTRUCTION SMES

Lean construction is an approach to managing the performance of construction activities where maximum value is achieved with reduced wastage and lean construction draws principles of Lean manufacturing, which originated from the Toyota Production System (Salem et al., 2006). Lean practices are used as an approach to develop and continuously improve production efficiency and to enhance the effectiveness of a business by reducing wasteful practices and improving efficiency (Majava & Ojanperä, 2017). Furthermore, lean practices enable firms to satisfy customer expectations while reducing cost and wastage at the same time (Bhamu & Sangwan, 2014). Lean Construction (LC) has been widely used in several industries, including building, road infrastructure, sanitation, mining, industrial facilities, and energy and oil projects (Erazo-Rondinel & Huaman-Orosco, 2021).

In many countries, the construction industry will be categorized into a few numbers of large companies and a very large number of SMEs (Tezel et al., 2020). Globally, SMEs represent 90% of businesses and contribute to economic growth, job creation and support for larger companies in the construction industry (Ranadewa et al., 2015; Tezel et al., 2020). The definition of SMEs varies across countries due to factors like the economic conditions of the country, population, and government policies. According to Tezel et al. (2020), an organization which has fewer than 50 employees is a small company, and one that has between 50 and 249 employees it is considered a medium-sized company. SMEs are considered the backbone of many economies, as they are instrumental in promoting economic growth, reducing poverty, and fostering sustainable development (Erhan & Gaugas, 2022). SMEs in the construction industry face a variety of challenges, including limited access to financial resources, technological barriers, and the ability to adapt to rapidly changing market conditions. Implementing lean construction principles has emerged as a potential solution to mitigate these issues by minimizing various forms of waste (Islam et al., 2019).

LC at SMEs has also attracted little attention from researchers, evidenced by the limited number of publications that directly reference the use of LC within SMEs (Tezel at al., 2020). The application of lean principles in construction SMEs involves tailoring lean tools to the specific characteristics of these enterprises, considering factors such as size, financial capabilities, organizational culture, and human resource capacity (Ayarkwa & Agyekum, 2017).

3.2 BENEFITS OF LEAN IMPLEMENTED CONSTRUCTION SMES

Lean Construction methods can improve performance in the construction sector by addressing project-related issues and focusing on stakeholders and management to add value (Nwaki & Eze, 2020). Many countries see Lean Construction as an appropriate method that can save resources, decrease costs, speed up activities, and improve control (Ivina & Olsson, 2020). Lean construction methods, techniques, tools, and concepts could face value challenges in construction and offer a solution for the efficiency-based problem in the construction industry (Shaqour, 2022). Many project-related items could be enhanced after implementing Lean Construction tools, such as time saving, material waste reduction, labor waste reduction, and space-cost saving (Reinbold et al., 2018). Many studies have discussed the benefits of lean construction, and Table 1 will summarize them.

Table 1: Benefits of Lean Construction in SMEs

Benefits Group	Benefit	Reference
Environmental benefits	Safety control improvements	[1]
	Time, cost, and material waste reduction	[2], [3]
	Material waste reduction	[3], [4]
	Improve the quality of the environment	[5]
	Preventing pollution and emissions	[6]
	Material storage control (access and inventor)	[1]
	Reduction of energy consumption	[5]
	Water conservation	[4]
	Enhancing work environment	[7]

Benefits Group	Benefit	Reference
Economic benefits	Time reduction	[1], [8]
	Cost reduction	[1], [3], [8]
	Improve quality	[4], [8]
	Increase productivity	[1]
	Rework minimization	[7]
	Improve prediction of risks	[7], [9]
	Improving safety	[7]
	Improved planning	[9]
	Improve process control	[9]
	Labor cost reduction	[9]
	Value achievement	[9]
	improving life-cycle cost	[9]
	Reduction of rework	[9]
Social benefits	Customer satisfaction	[1]
	Employee satisfaction	[1]
	Minimization of conflicts	[1], [3]
	Improve communication between project stakeholders	[3]
	Enhancing transparency	[4]
	Improving decision making	[3]
	Continues improvements	[3]
	Enhancing teamwork	[3]
	Valuing relationships	[9]

[1] - (Sarhan et al., 2017), [2] - (Ghosh & Bhattacharjee, 2014), [3] - (Silvius et al., 2017), [4] - (Ogunbiyi et al., 2014), [5] - (Saieg et al., 2018), [6] - (Salem et al., 2014), [7] - (Maradzano et al., 2019), [8] - (Ansah & Sorooshian, 2017), [9] - (Ivina & Olsson, 2020)

Table 1 highlights the key benefits of Lean implementation in construction, categorized into environmental, economic, and social benefits. Environmentally, Lean techniques contribute to waste reduction, pollution prevention, energy conservation, and improved safety and material management. Economically, they enhance efficiency by reducing time, costs, rework, and labour expenses while improving productivity, quality, and risk management. Socially, Lean fosters better communication, transparency, teamwork, and overall stakeholder satisfaction, minimizing conflicts and enhancing decision-making. Collectively, these benefits emphasize Lean's role in promoting sustainability, efficiency, and collaboration within the construction industry.

3.3 CHALLENGES OF LEAN IMPLEMENTED CONSTRUCTION SMES

The adoption of Lean principles within SMEs in the construction sector is fraught with numerous challenges, many of which stem from resource constraints, organisational limitations, and a lack of strategic integration. One significant challenge is the lack of time to implement Lean in ongoing projects, as SMEs often operate under tight schedules and financial constraints that prioritise immediate project deliverables over process improvements (Salvatierra et al., 2015). Further, client satisfaction in construction SMEs is a crucial issue in lean implemented construction SMEs. The real need of the clients is not being fulfilled as the lean implementation is not customized to the specific needs of the clients (Sergeeva, 2022). Another critical challenge is the inability to measure

performance and team progress, which hampers the ability of SMEs to assess the effectiveness of Lean implementation (Koohestani et al., 2020). Performance metrics are essential for continuous improvement, yet many SMEs lack the necessary tools and frameworks to systematically evaluate their Lean initiatives (Aslam et al., 2020). The absence of clear performance indicators not only diminishes accountability but also makes it difficult to justify further investments in Lean practices. This issue is closely linked to the low ability of personnel to recognise waste, as employees may lack the training to identify inefficiencies within workflows (Cerveró-Romero et al., 2013; Bashir et al., 2015). Without this fundamental awareness, Lean strategies risk becoming ineffective, as inefficiencies remain embedded within existing processes. Furthermore, low levels of Lean knowledge among university graduates present a systemic challenge. Many construction professionals enter the workforce with limited exposure to Lean principles, resulting in a workforce that is ill-equipped to drive Lean implementation (Murguia, 2019; Thomas et al., 2015). This knowledge gap necessitates extensive in-house training, which SMEs may struggle to provide due to resource constraints.

Compounding these difficulties is the tendency of some SMEs to replicate another organisation's Lean strategy without tailoring it to their specific needs. While benchmarking against successful Lean adopters can provide insights, blindly imitating methodologies without considering organisational context can lead to inefficiencies and misalignment with business objectives (Almanei et al., 2017; Kawish, 2017). Similarly, the lack of leadership and empowerment of personnel presents a substantial barrier, as effective Lean implementation requires strong managerial support and a participatory work culture (Huaman-Orosco & Erazo-Rondinel, 2021). In SMEs, where leadership structures are often less formalised, decision-making tends to be concentrated at the top, limiting employees' ability to contribute to Lean initiatives. This hierarchical approach can stifle innovation and reduce engagement with Lean principles at the operational level.

Moreover, Lean adoption in SMEs is often hindered by local rather than global flow optimisation, where firms focus on improving isolated processes rather than considering the broader supply chain and project-wide coordination (Bashir et al., 2015; Wandahl, 2014). This narrow focus prevents Lean from delivering its full benefits, as bottlenecks persist in areas that are not addressed holistically. Additionally, the lack of collaboration among project stakeholders exacerbates inefficiencies, as fragmented communication and misaligned objectives hinder the seamless integration of Lean processes (Gomez et al., 2018). Without early-stage collaboration involving all stakeholders including suppliers, subcontractors, and designers' lean efforts may be undermined by conflicting priorities and inadequate information sharing.

3.4 FACTORS AFFECTING CLIENT SATISFACTION IN LEAN IMPLEMENTED CONSTRUCTION SMES

Even though there are so many studies that have proved the benefits of lean implementation to the construction SMEs due to poor service design and an over focus on efficiency, lean implementation can fail (Radnor & Osborne, 2013). The adoption of lean manufacturing techniques has garnered substantial interest in recent years, especially within the construction sector, as a strategy to improve efficiency and minimize waste (Demirkesen & Bayhan, 2022). Nevertheless, the success rate of lean implementation has been quite unsatisfactory, with studies indicating that up to 90% of lean initiatives fail to be sustained beyond the first three years of their introduction (Xing et al., 2021).

One of the primary problems that has not been addressed is client satisfaction in construction SMEs. The real needs of the clients are not being fulfilled, as the lean implementation is not customized to the specific needs of the clients (Sergeeva, 2022). The construction industry is inherently complex and dynamic, with projects often facing a myriad of uncertainties, complex supply chains, and varying site conditions (Bayhan et al., 2019). This complexity and varying conditions can pose significant challenges to the effective implementation of lean principles, which are often more easily applied in a manufacturing setting. Furthermore, the lack of knowledge and expertise in lean methodologies among construction professionals exacerbates the challenge, further impeding successful implementation (Bayhan et al., 2019).

To overcome these obstacles, construction companies need to take a more comprehensive approach to lean implementation, focusing not just on process-level adjustments but also on cultivating a culture that encourages continuous improvement and the elimination of waste.

3.5 CLIENT SATISFACTION MODELS

The client is the owner of a construction project or the buyer/seller of goods or services (Challender & Whitaker, 2019). Client satisfaction refers to meeting or exceeding their expectations with services or products (Riak & Bill, 2022). Accordingly, client satisfaction is based on recognizing and addressing their requirements (Durdyev et al., 2018; Rahman & Alzubi, 2015). Customer satisfaction is often associated with performance in the construction sector and companies with high client satisfaction ratings get a competitive advantage (Alshihre et al., 2020). Moreover, failure to communicate effectively and meet deadlines may result in dissatisfaction on both sides of a construction contract (Obonadhuze et al., 2021). Client satisfaction is an emotional response when realizations exceed expectations (Sulistyawati & Listiyanti, 2024). Client satisfaction models have evolved significantly over the years, reflecting a diverse range of approaches and methodologies tailored to various sectors and contexts. These models are crucial for understanding the factors that contribute to client satisfaction and for improving service delivery across industries.

One foundational model is the Kano model, introduced by Noriaki Kano, further enriches the discourse on client satisfaction by categorizing customer needs into five distinct types: basic, performance, excitement, indifferent, and reverse qualities. This classification helps organizations prioritize features and services that enhance customer satisfaction (Wang et al., 2019; Rahaju & Dewi, 2014). The applicability of the Kano model extends beyond product development to service industries, where understanding the nuances of customer expectations can lead to improved satisfaction outcomes.

Moreover, the SERVQUAL framework, which assesses service quality through dimensions such as reliability, assurance, tangibles, empathy, and responsiveness, has been widely utilized to evaluate client satisfaction in various sectors, including healthcare and retail (Luruli et al., 2016) This framework allows organizations to identify gaps between customer expectations and actual service delivery, thereby facilitating targeted improvements.

American Customer Satisfaction Index (ACSI) serves as a benchmark for measuring customer satisfaction across various sectors. It emphasizes the relationship between perceived quality, customer satisfaction, and customer loyalty, suggesting that higher

satisfaction leads to increased loyalty and, consequently, better financial performance for firms (Liu et al., 2020; Wang et al., 2021). The ACSI methodology captures the nuances of customer expectations, perceived quality, and perceived value, all of which contribute to the overall satisfaction score. The resulting data enables businesses to identify areas for improvement, refine their strategies, and benchmark their performance against competitors, enhancing their competitiveness and fostering sustainable growth (Wang et al., 2021; Sha et al., 2022). This insight is invaluable for prioritizing investments in product development, service enhancements, and customer relationship management (Liu et al., 2020). Figure 2 illustrates the ACSI model.

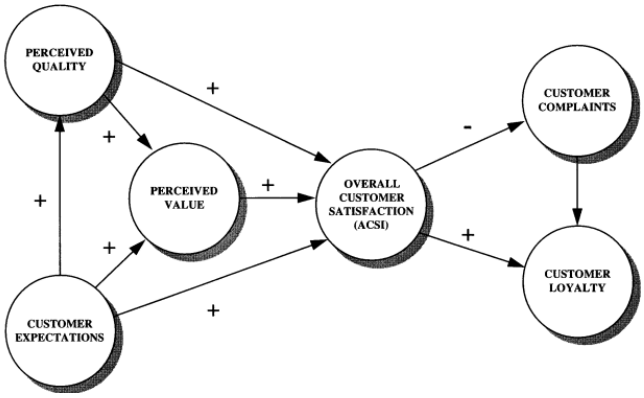

Figure 2: ACSI model (Source: Fornell et al., 1996)

Furthermore, the ACSI model's proven track record in various sectors underscores its robustness and reliability as a tool for measuring customer satisfaction (Sha et al., 2022). Therefore, by integrating the ACSI framework in lean implemented construction SMEs can gain actionable insights into client satisfaction, enabling them to refine their processes, enhance service quality, and achieve a competitive edge in the market.

3.6 CONCEPTUAL FRAMEWORK

The literature review revealed a clear need to establish a client satisfaction model specifically for construction SMEs that have adopted lean principles. Accordingly, the conceptual framework presented in Figure 3 was developed based on the insights gained from the literature review.

This framework offers a structured approach to identifying and understanding the factors that influence client satisfaction in construction SMEs that have implemented lean principles. It outlines key elements, including lean principles, the benefits of lean implementation in SMEs, barriers to adoption, factors affecting client satisfaction, and reasons for failing to achieve client satisfaction. Furthermore, the framework proposes a model for identifying these influencing factors and enhancing client satisfaction in construction projects.

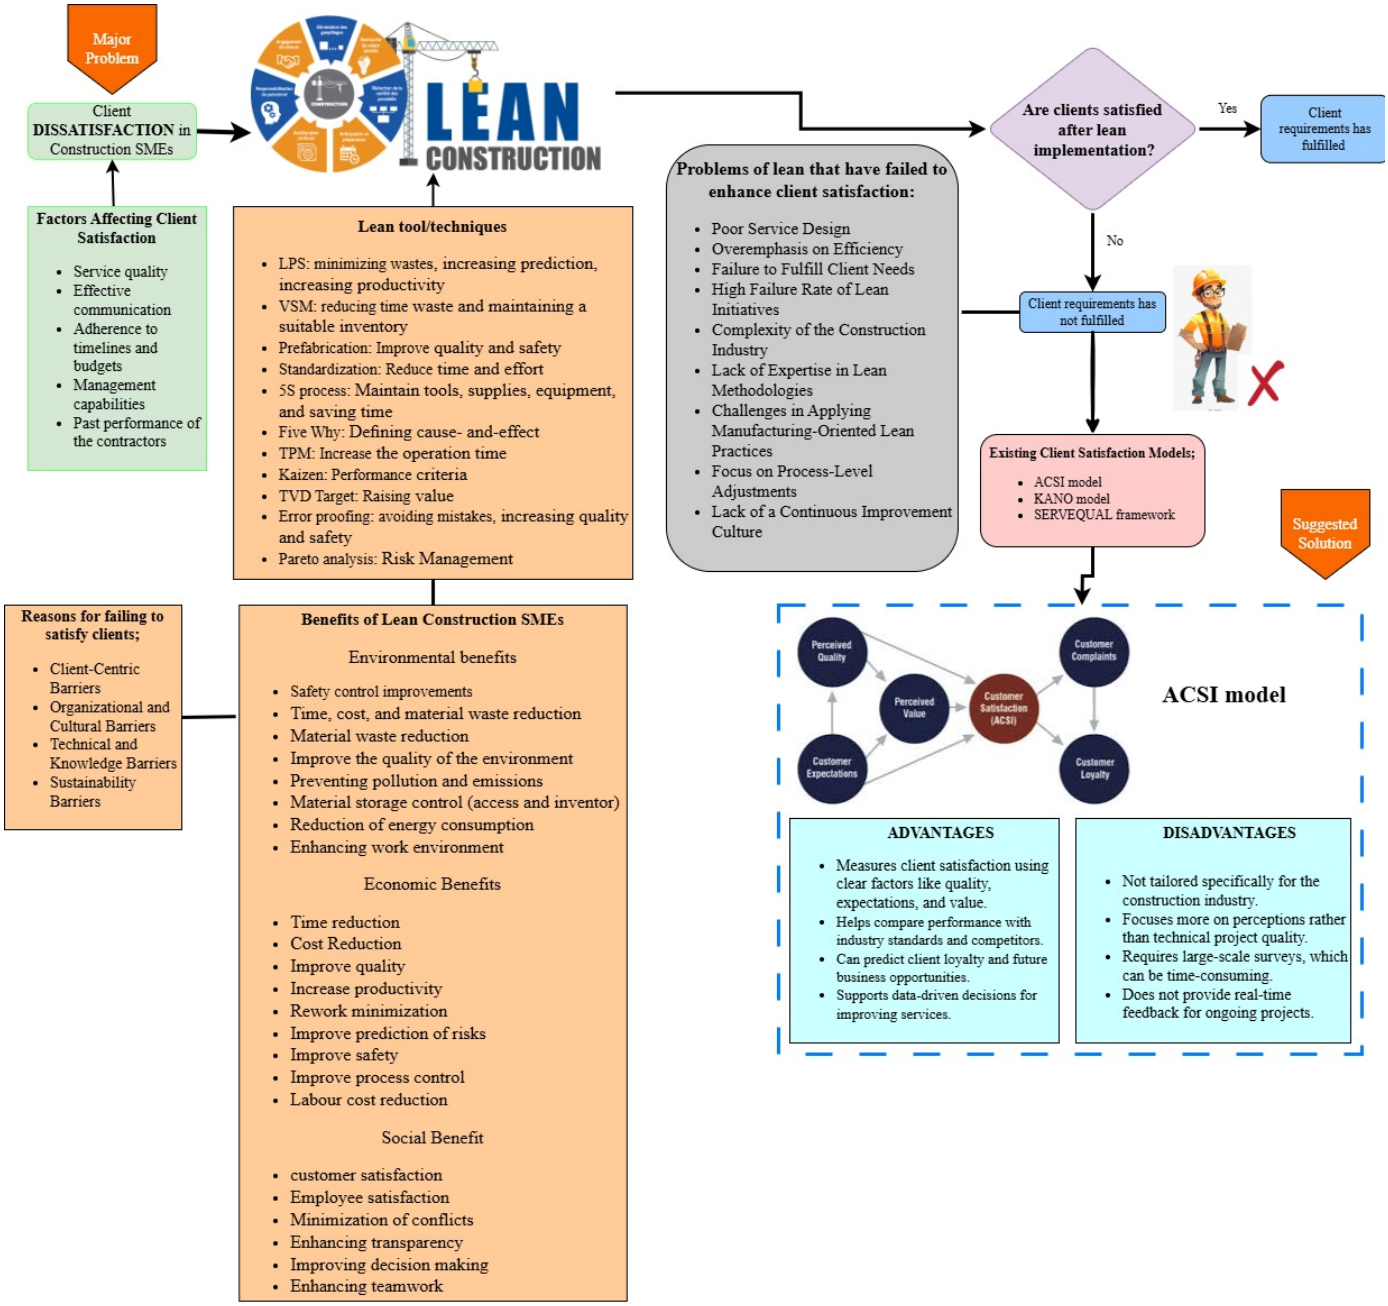

Figure 3: Framework for client satisfaction model in lean implemented construction SMEs

ACSI model is selected over other client satisfaction models due to its comprehensive, adaptable, and empirically validated structure, which makes it particularly suitable for application in lean implemented construction SMEs. Unlike generic satisfaction models, the ACSI model provides a robust, cause and effect framework that links client expectations, perceived quality, and value to satisfaction, and subsequently to client loyalty and complaint behaviour. This alignment is especially beneficial for construction SMEs adopting lean principles, as it enables the evaluation of how lean strategies directly influence client satisfaction outcomes. The model's flexibility allows for the integration of lean-specific factors such as process efficiency, waste minimisation, and continuous improvement. Through this framework, construction SMEs can not only assess the current level of client satisfaction but also identify specific lean-related practices that

enhance value delivery, thereby fostering long-term relationships and competitive advantage in the industry.

4. CONCLUSIONS

Despite the increasing adoption of lean principles in construction SMEs, there remains a significant gap in research addressing the causes of low client satisfaction in these organisations. This study aimed to bridge this gap by developing a framework for a client satisfaction model tailored to lean implemented construction SMEs. Through a literature review, key factors influencing client satisfaction were identified, along with the benefits, barriers, and challenges associated with lean implementation in SMEs. The study proposes the adoption of the ACSI as the basis for the client satisfaction model, emphasising the relationship between perceived quality, customer satisfaction, and customer loyalty. The model suggests that higher client satisfaction leads to increased loyalty, which in turn enhances financial performance, making it a valuable approach for improving business sustainability in lean implemented construction SMEs.

This study contributes to both academic knowledge and industry practice by offering a conceptual framework that can serve as a foundation for improving client satisfaction in lean implemented construction SMEs. From a theoretical perspective, it enriches the existing literature by identifying critical factors affecting client satisfaction within the lean construction context. In practice, the proposed framework, grounded in the ACSI model, provides SMEs with strategic insights to enhance their lean implementation processes and client engagement strategies. Future research should focus on empirically validating the framework through case studies and stakeholder interviews to refine its applicability and effectiveness in real-world construction projects.

COMMUNITY BENEFIT AND ENGAGEMENT FRAMEWORKS IN AUSTRALIAN RENEWABLE ENERGY TRANSITION: A THEMATIC ANALYSIS

Umesha Weerapperuma[1], Navodana Rodrigo[2], M.K.C.S. Wijewickrama[3] and George Zillante[4]

ABSTRACT

The renewable energy transition has become a core priority in Australia over the past few decades, with a target to achieve 82% renewable energy in the country's electricity grids by 2030. The social dimension, along with community acceptance of renewable infrastructure developments, is essential. Several publicly accessible documents guide decision-making at the Federal and State levels, as well as the roles of key stakeholders involved in the energy transition. However, obtaining the social license to operate remains a significant challenge, as it is hindered by the gap between strategic suggestions and actual implementation in practice. Therefore, this study employed the Thematic Analysis approach inductively, using NVivo, to collect textual data from documents and frameworks published by state governments and reputable non-governmental bodies in Australia since 2020. The thematic analysis of paragraphs was conducted under four categories (parent nodes): benefits sharing mechanisms, equity and inclusion, transparency and accountability, and monitoring and evaluation mechanisms. Thereafter, maps were generated to illustrate sub-themes (child nodes) along with referenced documents. In practice, the results underscore the need for more integrated strategies that align with timelines and involve stakeholders, including developers, policymakers, and communities, in future guidelines. Furthermore, the thematic analysis approach adopted in this study provides a proven methodology for analysing differently organised frameworks and reports. As analysis in academic research using industry frameworks is rare in the renewable energy sector from a social perspective, this provides a basis for future research. The created maps could be beneficially used and generalised for future frameworks.

Keywords: *Community Benefits; Community Engagement; Renewable Energy Transition; Thematic Analysis.*

1. INTRODUCTION

Recently, the Australian government enacted laws in 2022 to reduce carbon emissions by 43% compared to 2005 levels by 2030, aiming to achieve net zero by 2050 (Australian Trade and Investment Commission, 2023). The redesigned safety mechanism is a tool designed to facilitate the execution of this objective by directing Australia's top greenhouse gas emitters to keep their net emissions at or below a set baseline. This baseline is reduced annually, and those that exceed it must manage their excess emissions, including by purchasing and surrendering Australian carbon credit units (Wells et al., 2018). The Australian Government aims for 82% renewable energy in the nation's electricity systems by 2030 (Department of Climate Change, Environment and Climate Action, 2022). Under the leadership of the recently elected Australian government, which has pledged to a more ambitious target of lowering national greenhouse gas (GHG) emissions by 43% by 2030, relative to 2005 levels, this transition to clean energy is anticipated to accelerate (Koskinen et al., 2023). The rapid transition has presented numerous challenges for grid and market operations; for instance, market estimates by the Australian Energy Market Operator have consistently underestimated the pace of the transition to clean energy (Funder et al., 2021).

Subsequently, renewable energy sources are revolutionising the production, distribution, and use of energy (Clean Energy Council, 2019). These systems have the capacity to overturn the current economic and social structure of energy delivery since they provide heat and power in different capacities (Bauwens et al., 2016). It has been suggested that shifting to decentralised and renewable energy generation is a way to address climate change and boost energy supply self-sufficiency (Rae & Bradley, 2012). Several studies disclose that the social dimension is important as the technology component to stress the need for community responses that are more predisposed to successful transition (Lennon et al., 2019; Soltani et al., 2021). Significantly, creating and sustaining a social licence and providing social value to communities are crucial prerequisites for the success of the renewable energy transition from an infrastructure perspective (Kola-Bezka, 2023, Lennon et al., 2019, Miller et al., 2015). As a result, several stakeholders involved in energy research and policy concur that transdisciplinary consortia must lead energy transitions under the direction of social science concerns about the human dimensions of energy transition (Chodkowska-Miszczuk et al., 2021; Lennon et al., 2019; Stephanides et al., 2019). These methods are crucial for achieving community acceptance of green energy solutions among members of a social unit. There are several publicly accessible documents that guide decision-making at the Federal and state levels, as well as the roles of key stakeholders involved in the energy transition. Nevertheless, the content of the documents tends to focus predominantly on a single area (e.g., benefit sharing), or exhibits repetitiveness, overlapping subject areas, and multiple facts that lack practical applicability (Hicks & Mallee, 2023; NSW Department of Planning and Environment, 2023). Therefore, this paper aims to answer the research question, "How *have community benefit and engagement frameworks published after 2020 addressed key aspects of community engagement in the Australian renewable energy transition?*" through a qualitative research approach. Consequently, it highlights the need to identify these overlaps and gaps, particularly in relation to the practical implementation of community benefit and engagement frameworks, in order to guide future research in addressing key concepts within these frameworks and to stimulate meaningful community engagement.

Section 2 presents an overview of the selected documents on community benefits and engagement in Australia after 2020. The adopted methodology for identifying the key themes via NVivo is discussed in Section 3. Analysis and discussion of the findings are presented in Section 4, where the identified key themes (codes) are discussed under four main categories (see Sections 4.1, 4.2, 4.3, and 4.4). The conclusion, along with its limitations and the way forward, is presented in Section 5. Finally, Sections 6 and 7 are allocated for acknowledgements and references used in this paper.

2. COMMUNITY BENEFITS AND ENGAGEMENT FRAMEWORKS

In the past few decades, the Australian Government has considered various policies to mitigate the consequences of climate change, including the emissions trading system, the carbon pollution reduction scheme, and the carbon tax, among others. According to records, all of these have different successive levels and were never implemented. Accordingly, the federal and state governments, as well as various reputable non-governmental organisations (such as the Clean Energy Council and RE-Alliance), have published strategies to guide all aspects of the renewable energy transition. As this paper focuses on the communities and their engagement in the energy transition, seven recently published documents (publicly available) were selected, particularly due to their emphasis on heightened climate action goals, post-COVID recovery plans, and shifts in political will. Considering public accessibility, trustworthiness, and the reputation of the publishing organisations (both state governments and non-governmental organisations), the analysis was limited to seven documents. Table 1 presents the details of the selected seven documents for this analysis, along with their publishing organisations, year of publication, and an overview of the content.

Table 1: Overview for community benefits and engagement frameworks (after 2020)

No	Document	Organisation and Source	Year	Overview
A.	Community Benefits Handbook	RE-Alliance (Re-Alliance, 2024)	August 2024	Emphasises the importance of local engagement in decision-making processes, offers insights into community enhancement funds that can support local initiatives, and highlights opportunities for co-investment and ownership in renewable projects. It also highlights the significance of including First Nations' perspectives to ensure that their rights and knowledge are respected, ultimately aiming for a collaborative approach.
B.	Community Benefits Framework	Queensland Hydro (Queensland Hydro, 2024)	August 2024	Presents sustainable relationships with local communities by prioritising engagement, transparency, and collaboration, while addressing the environmental, economic, and social needs through initiatives that benefit individuals and regional development.

No	Document	Organisation and Source	Year	Overview
C.	Energy and Jobs Plan: Local Energy Partnerships	Queensland Department of Energy and Climate (Queensland Government, 2024)	May 2024	Outlines Queensland's commitment to engaging regional communities in the energy transformation by prioritising local voices, choices, and benefits through a framework that encourages collaboration, resource allocation, and the improvement of renewable energy practices, with a focus on supporting First Nations and local councils.
D.	Renewable Energy Development in Tasmania: Guideline for Community Engagement, Benefit Sharing and Local Procurement	Tasmania Department of State Growth (Tasmania Department of State Growth, 2024)	May 2024	Presents best practices for renewable energy development in Tasmania, emphasising effective community involvement, the importance of understanding social contexts, and mechanisms for sharing benefits. It aims to empower Tasmanian communities to participate actively in the renewable energy sector while ensuring that local businesses and residents gain tangible advantages.
E.	Draft Benefits Sharing Guideline: Energy Policy Framework	NSW Department of Planning and Environment (NSW Department of Planning and Environment, 2023)	November 2023	Provides a comprehensive policy framework aimed at ensuring equitable distribution of benefits from large-scale renewable energy projects in NSW, emphasising community involvement, particularly that of Aboriginal communities, and promoting mechanisms for sharing economic and social benefits to enhance local resilience and support.
F.	Regional Benefit Sharing Discussion Paper	Community Power Agency (Hicks & Mallee, 2023)	October 2023	Explores strategic frameworks for community benefit sharing in regions hosting multiple renewable energy projects, emphasising the need for coordinated approaches to enhance local engagement and maximise positive impacts while minimising community disempowerment and engagement fatigue.
G.	Community Engagement and Benefits Sharing in Renewable Energy Development in Victoria	Victoria Department of Energy, Environment and Climate Change (Department of Energy Environment and Climate Change, 2021)	July 2021	Presents a comprehensive framework for renewable energy developers, emphasising the necessity of active community engagement and benefit-sharing strategies to obtain social license to operate. It outlines best practices for social impact assessments and encourages innovative approaches

These documents frequently refer to case studies, best practice frameworks, and empirical findings to strengthen their recommendations. For example, "Community Engagement and Benefits Sharing in Renewable Energy Development in Victoria" and "A Guide to Benefit Sharing Options for Renewable Energy Projects" include case studies that illustrate successful benefit-sharing mechanisms and community engagement strategies. Moreover, many documents adopt a principle-based approach to maintain the core values of social science content, including benefits sharing mechanisms, equity and inclusion, transparency, accountability, and monitoring and evaluation. Batidzirai et al.(2021) evidence that principle-based approaches protect community rights, especially when working with marginalised groups, ensuring that content does not cause harm or exploitation. Moreover, that consistency facilitates comparison, replication and validation of findings (Walker et al., 2010).

3. METHODOLOGY

Thematic analysis was used to identify, analyse and interpret patterns (themes) within the textual data in the selected seven documents. Mainly, thematic analysis can be conducted inductively (letting themes emerge from the data) or deductively (following existing theory or frameworks) (Rosenthal, 2016). As this paper intends to collect textual data from existing documents, thematic analysis was conducted inductively. Moreover, NVivo 15 software was used to analyse the data as it enables easier extraction and categorisation of key themes with reference to the relevant document (via each code connected to the relevant document) (Krishnan et al., 2025). Figure 1 illustrates the flowchart of the executed methodology.

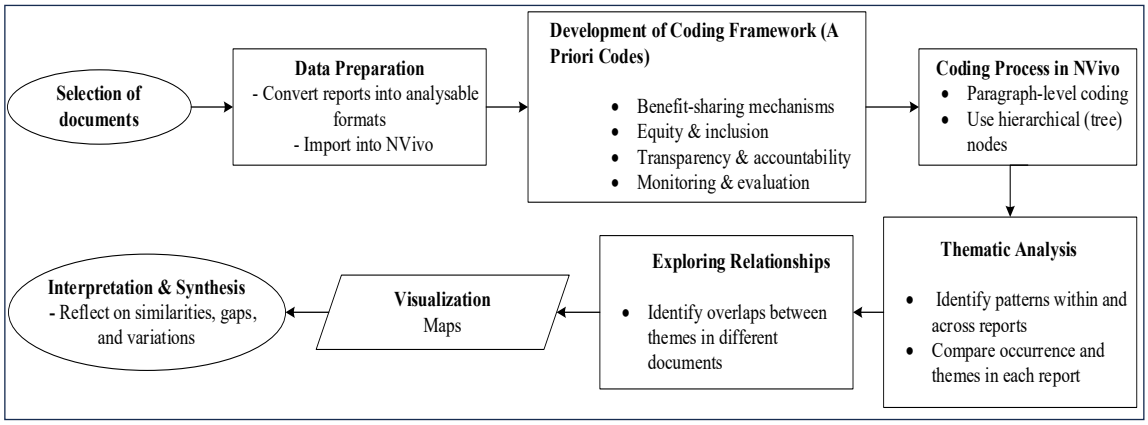

Figure 1: Methodology flowchart

Firstly, the seven documents were selected based on the main criteria of public accessibility, trustworthiness, the reputation of the publishing organisations (as state governments and non-government bodies), and publication after 2020. Then the files were imported into the NVivo software with their analysable formats. As per the third step in the flowchart (refer to Figure 1), coding framework was developed. The coding process was based on hierarchical nodes; it refers to the way nodes are organised into a parent-child structure. For example, parent nodes represent broader themes, such as benefits-sharing mechanisms, and child nodes fall under these parent nodes, representing more specific sub-themes, as seen in section 4.2. The four parent nodes were selected based on their prominence in both the reviewed documents and the broader literature on community engagement (Victoria Department of Energy Environment and Climate

Change, 2021; NSW Department of Planning and Environment, 2023; Tasmania Department of State Growth, 2024). Benefit-sharing mechanisms have emerged as a central theme, as ensuring the fair distribution of all aspects. Equity and inclusion were prioritised to reflect the importance of involving First Nations peoples, landowners, and other marginalised groups, ensuring that engagement processes are fair and inclusive. Transparency and accountability were identified as essential characteristics of good governance, as policy-supporting frameworks must demonstrate openness. Finally, monitoring and evaluation mechanisms were included as effective frameworks require systematic processes to track progress, assess outcomes, and enable continuous improvement after implementation. Other topics that emerged during analysis, such as technical considerations or project financing, were treated as sub-themes or supporting elements under these primary categories, where appropriate. The findings were visualised via "Maps" in the NVivo software, as it offers more visual clarity than presenting numerical values alone. Figures 2, 3, 4, and 5 illustrate the thematic coding structure derived from the data. To enhance visual clarity, parent nodes are consistently coloured in red, while child nodes are presented in various colours to aid in the quick identification and differentiation of categories.

4. ANALYSIS AND DISCUSSION

This section presents the findings generated after thematic analysis, with a discussion of the obtained data. By critically analysing the structure according to a principles-based approach (under four parent codes) and strategic priorities, this section reveals the extent to which communities are positioned as active and/or passive beneficiaries in the transition process.

4.1 DEFINITIONS OF "COMMUNITY"

The concept of community and its related forms of engagement have multiple meanings. The community is not a place, a building, an organisation, or an exchange of information (Koirala et al., 2016; Rogers et al., 2008). In the renewable energy transition, communities consist of groups of citizens, social entrepreneurs, public authorities, and community organisations that are actively involved in the energy transition by jointly investing in, producing, selling, and distributing renewable energy (Boulogiorgou & Ktenidis, 2020). Table 2 presents the definitions of community provided in seven documents as they change according to the underlying assumptions and priorities when presenting strategies, i.e. "community", whether geographically surrounded residents or marginalised groups, First Nations peoples or whose voices are heard (Pons-Seres de Brauwer & Cohen, 2020; McMillan & Chavis, 1986).

Table 2: Definitions of "community"

A	"a group of individuals living in close proximity to renewable energy projects, who may share common interests, aspirations, or issues related to the projects."
B	"All individuals residing in the geographic area surrounding the proposed renewable energy project, including various interest groups and cultural demographics."
C	"The collective of stakeholders impacted by renewable energy projects, emphasising the importance of engaging these stakeholders to ensure."
D	"Residents, local businesses, and organisations are involved in renewable energy projects"

E "a geographic and social entity, highlighting the need for definitions to be site-specific, based on local demographics and relationships to renewable energy developments."

F "Various groups that reside in or are affected by renewable energy projects, stressing the importance of understanding local dynamics in benefit-sharing discussions."

G "Individuals and organisations within defined geographic areas, stressing the significance of diverse representation in engagement processes."

The "community" has been defined in consideration of three key aspects: the local population living near or affected by renewable energy infrastructure developments, diverse groups based on geographical areas, marginalised and First Nation peoples, and social and cultural perspectives that consider landscape value and heritage. Therefore, people who live in or are connected through shared interests, culture, or location affected by renewable energy infrastructure developments are recognised as a "community" in the context of community engagement and community benefits sharing. The following subsections present the method of aligning the selected documents with these aspects.

4.2 BENEFITS SHARING MECHANISMS

The concept, 'benefit sharing', concerns sharing the rewards of renewable energy developments with communities (NSW Department of Planning and Environment, 2023). This concept is based on a desire to establish and maintain positive long-term connections with the area and to be a stimulator of positive perception among the communities (Tasmania Department of State Growth, 2024). Figure 2 presents the codes (documents), and child nodes (sub-themes) associated with the benefits-sharing mechanism (parent node).

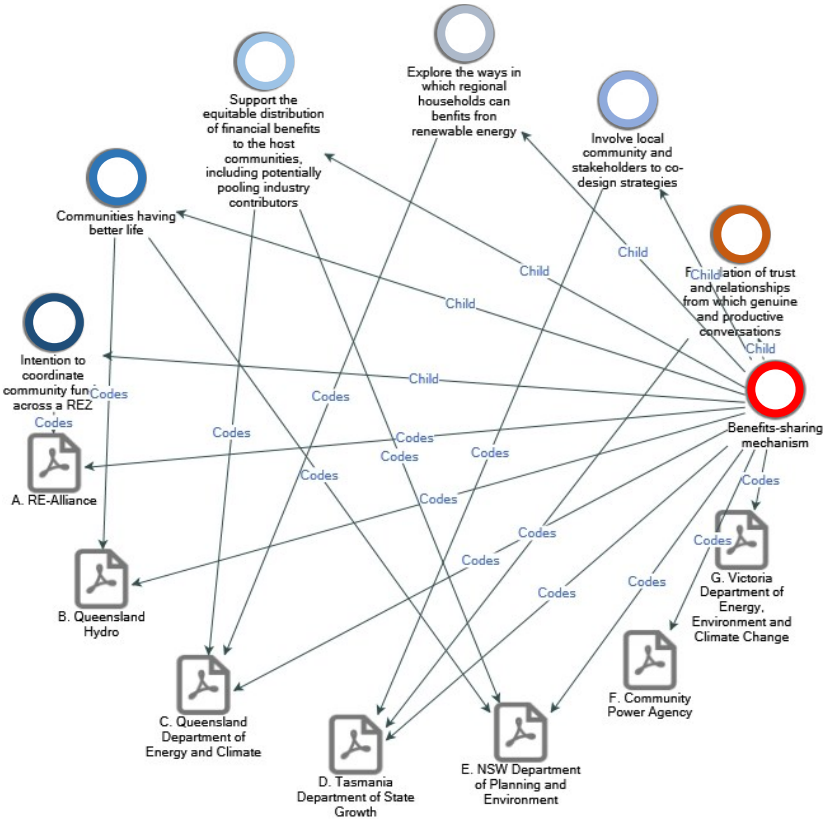

Figure 2: Benefits sharing mechanisms – nodes

The NSW benefits sharing guidelines specify that sharing initiatives offer a means of enhancing benefits for the community in the vicinity of and affected by renewable energy developments. This includes communities that may be affected by projects nearby, as well as members of the broader local community that host the development. All seven documents mentioned 'benefits sharing' as a key concept, along with strategies for implementing it. For instance, building community solar projects for local businesses, developing micro grids for the community, allocating some portion of the project's profit for a revolving fund that can operate in perpetuity, tourism and education programmes, and adding optical fibres to transmission towers are a few strategies to provide a better life for communities.

Ultimately, developers/government expect to create a foundation from genuine contributions and productive conversations (Tasmania Department of State Growth, 2024; Hicks & Mallee, 2023). Furthermore, equitably distributing and coordinating community funds across Renewable Energy Zones (REZs) is also a key consideration in benefits sharing (NSW Department of Planning and Environment, 2023). Nevertheless, power imbalances between stakeholders are a noticeable loophole that critically reflects from the analysed frameworks, i.e. who decides on benefits distribution?

4.3 EQUITY AND INCLUSION

A wind farm project-based research paper found that the "local host community perceived there to be 'winners and losers' from the project, with the 'winners' being host landholders who would receive an annual income and the 'losers' being neighbouring landholders who would be impacted but receive no direct benefits" (Re-Alliance, 2024). In recent years, this perceived inequity has been a cause for increasingly shared agreements between energy project proponents and neighbouring landholders. This theme mainly implies equitable access to opportunities for all communities (Queensland Hydro, 2024).

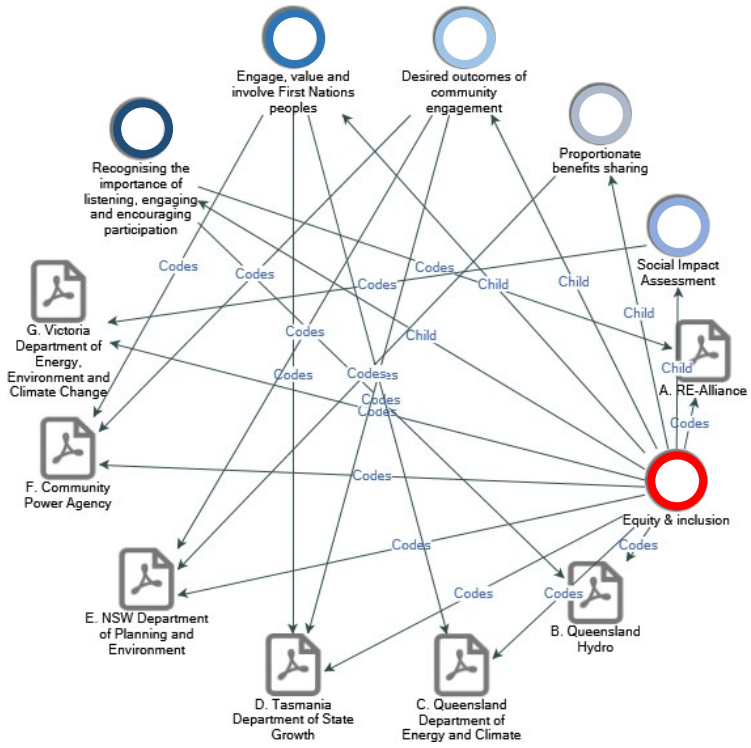

Figure 3: Equity and inclusion - nodes

Figure 3 presents the codes (documents) and child nodes (sub-themes) connected to the equity and inclusion (parent node). Equity and inclusion have sometimes been treated as overlapping, while in other instances as a combined theme. Nevertheless, both aspects are consistently addressed in all the selected documents. For instance, equity and inclusiveness of Aboriginal (First Nations people) through engagement and policy initiatives is a positive approach identified by the Tasmanian government (Tasmania Department of State Growth, 2024).

Accordingly, genuine shared decision-making means that the Tasmanian Aboriginal people are central in all decision-making. Simply, this ensures that First Nations people have ownership opportunities, not just consultation, and offers discounted energy rates to all residents, not just a select few. While all the analysed documents addressed the principles of equity and inclusion at a conceptual level, the critical challenge remains in translating these recommendations into practice.

4.4 TRANSPARENCY AND ACCOUNTABILITY

Adhering to transparent processes and unbiased procedures with accountability provides all the people in the community with an equal chance to engage, benefit and contribute to the energy transition (Queensland Hydro, 2024). Accordingly, developers are committed to openly sharing the outcomes of their initiatives and investments with the community (Queensland Hydro, 2024). This transparency ensures that our stakeholders are informed about the progress and outcomes of the renewable projects. Figure 4 presents the codes (documents) and child nodes (sub-themes) connected to the transparency and accountability (parent node).

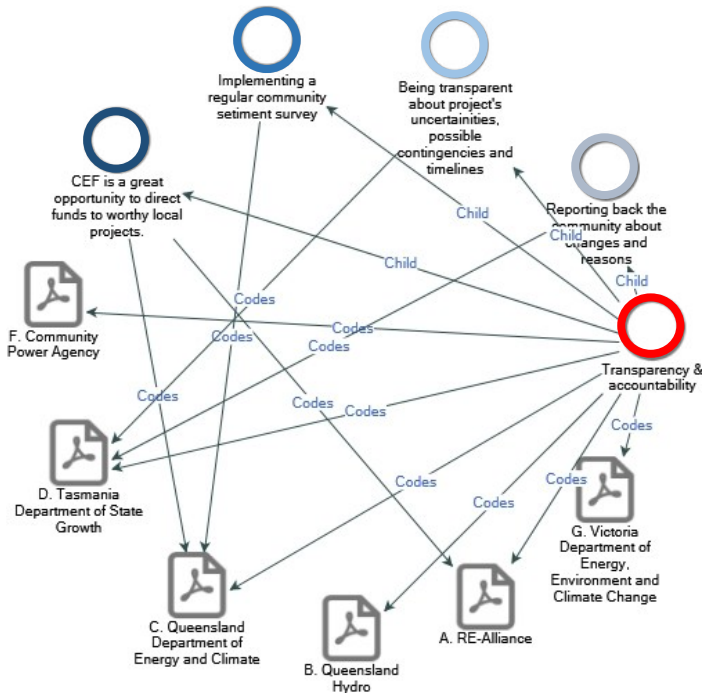

Figure 4: Transparency and accountability

While all the documents discuss the importance of transparency, in many cases, transparency is maintained primarily at the level of information provision rather than through deeper forms of engagement, such as consultation, collaboration, or shared

decision-making. As a result, transparency often remains limited to passive communication rather than active community empowerment, highlighting the need for more systematic mechanisms that embed transparency throughout all stages of engagement.

4.5 MONITORING AND EVALUATION MECHANISMS

Monitoring and evaluation of the community engagement or benefits sharing process's effectiveness were implicitly outlined in the six documents and did not appear in Re-Alliance (2024). It is important to involve communities, stakeholders, and developers in regular review and evaluation processes to assess the effectiveness of the implemented strategies. Ongoing feedback mechanisms should be established to adapt practices as needed, ensuring that projects continue to meet evolving community needs and expectations while remaining strategically aligned with the energy transition goals (Hicks & Mallee, 2023). Figure 5 presents the codes (documents) and child nodes (sub-themes) connected to the monitoring and evaluation mechanisms (parent node).

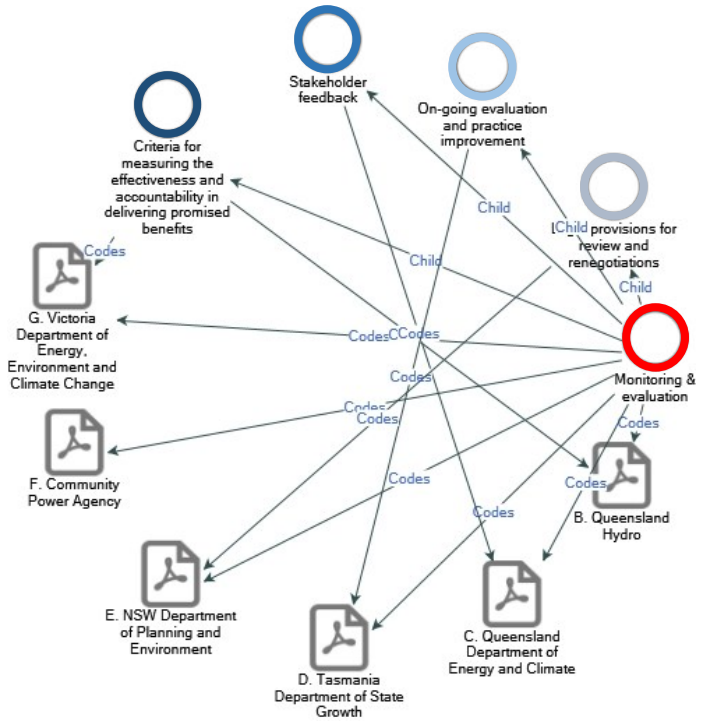

Figure 5: Monitoring and evaluation

Accordingly, coded documents have discussed broader recommendations for monitoring and evaluation without a specific timeline and stakeholder involvement. For instance, monitoring and assessing after an issue develops or while a new plan is being established, occasional community focus groups or surveys and evaluation at significant long-term milestones, are standard practices (Victoria Department of Energy Environment and Climate Change, 2021).

Nevertheless, the way of generalising the recommendations can be considered a gap that needs to be addressed. Without precise monitoring and evaluation practices, it is challenging to ensure accountability, measure outcomes, or adjust strategies in response to community feedback and evolving circumstances. With this, a distance will be created between theory and practice.

5. CONCLUSIONS, LIMITATIONS AND WAYS FORWARD

There are different types of reports, articles, and discussion papers presented by the Federal/State governments, non-governmental organisations (i.e. Clean Energy Council, RE-Alliance) to guide stimulating community engagement and benefits sharing mechanisms in the renewable energy transition. Nevertheless, these existing documents overlap the same facts, lacking important details or combining different facts, while developing broader strategies that lack defined timelines or stakeholder accountability. Therefore, this paper aimed to address the research question specified in Section 1. Accordingly, the key aspects were identified using a principles-based approach, focusing on benefits sharing mechanisms, equity and inclusion, transparency and accountability, and monitoring and evaluation. Mainly, six sub-themes were identified for "benefits sharing mechanisms" in all seven documents, with 13 references. "Equity and inclusion" for the communities has been implicitly mentioned in six documents. There were four and five sub-themes identified under "monitoring and evaluation" and "transparency and accountability", respectively, with a maximum of one sub-theme connected to two documents. The analysis revealed a lack of consistency across the documents, with noticeable overlaps and repetitions between key factors. Concepts like equity were sometimes discussed narrowly in the context of financial benefit-sharing, overlooking broader social benefits. This inconsistency risks marginalising important aspects of community engagement and highlights the need for a more systematic way of presenting findings.

Conducting an independent analysis to address the research question, this study provides an overview of the key aspects included in existing frameworks and documents. More significantly, the thematic analysis approach adopted in this study offers a proven methodology for analysing differently organised frameworks/reports. In practice, the results underscore the need for more integrated strategies that align with the project timeline and involve stakeholders, including developers, policymakers, and communities. As limitations of this study, document selection bias, along with the published time (after 2020) and selection criteria, are noted. Furthermore, although NVivo assists in managing data, the coding process remains subjective, relying on researchers' judgment. As this type of analysis in academic research using industry frameworks is rare in the renewable energy sector from a social perspective, this provides a basis for developing greater accuracy through additional documents using other techniques, such as Topic Modelling. Further, these created maps could be used and generalised for future frameworks.

COMPARISON OF LEGISLATION OF UK AND SRI LANKA FOR BETTER IMPLEMENTATION OF CIRCULAR ECONOMY IN SRI LANKAN CONSTRUCTION INDUSTRY

M.D.T.E. Abeynayake[1] and B.A.K.S. Perera[2]

ABSTRACT

The construction industry (CI)is a significant contributor to worldwide environmental pollution while being a substantial user of finite resources and a substantial generator of waste. The Circular Economy (CE) concept aims to manage raw materials and minimise waste generation. The lack of relevant laws and regulations is a significant barrier to the implementation of CE. It is necessary to have a systematic approach to design and implement CE laws to cover the multi-sector dimensions of the CE concept. Limited research is available on laws and regulations related to the CE in the global and Sri Lankan contexts. This study aims to compare the legislation provisions for CE in CI in Sri Lanka and the United Kingdom (UK) for the better implementation of CE in CI in Sri Lanka. The study investigates how CE principles can be integrated into construction strategies in Sri Lanka, drawing from existing legal frameworks in the UK, and conducted through a review of legislation and policies. Findings reveal that the UK has made significant progress in embedding CE principles through legislative support and sustainable construction regulations. However, Sri Lanka is still in the early stages of this transition. This study further identified legal pitfalls in integrating CE practices, including gaps in the enforcement of CE within the Sri Lankan CI. The study concludes with key recommendations for introducing laws, legally supported CE practices in Sri Lanka, CE new legal reforms, and incorporation of CE principles into construction law.

Keywords: *Construction Industry; Circular Economy; Law; Sri Lanka; UK.*

1. INTRODUCTION

The CI sector notably accounts for over 30% of natural resource extraction and approximately 25% of global solid waste production (Benachio et al., 2020). CE practices contribute to emission reductions, decreased waste generation, and sustained economic growth (Kanwar, 2023). The CE presents a viable strategy for fostering long-term environmental sustainability by aligning economic activities with ecological principles (Geissdoerfer et al., 2017). The CI is a major contributor to environmental degradation, resource consumption, and waste generation. According to Jahan et al. (2022) the CE is

[1] Senior Lecturer, Department of Building Economics, University of Moratuwa, Sri Lanka, mabeynayake@uom.lk
[2] Senior Professor, Department of Building Economics, University of Moratuwa, Sri Lanka, kanchana@uom.lk

an economic model that promotes material cycling to reduce basic material use and misuse creation. It supports sustainability by adhering to the 3Rs: reduction, reuse, and recycling. Strategies including waste reduction during product design, preventative measures, maintenance, repair, reuse, and recycling can help reach these aims. CE manages losses by exploring alternative uses and resources stored for a long duration (Alhazmi et al., 2021). As explained by Velenturf et al. (2019), the "take-make-dispose" approach of the linear economy has been altered by diminishing the steps of "take" and "dispose" across closed-loop methods such as reusing, recycling, and regeneration in the CE concept. This transformation fosters new business opportunities in areas such as remanufacturing, refurbishing, and repair, thereby supporting economic growth across countries (Hailemariam & Erdiaw-Kwasie, 2023).

Wijewansha et al. (2021) examined the practical application CE principles during the early planning and post-construction phases of Sri Lanka's building industry. By integrating considerations of rebound effects into CE practices, stakeholders can better navigate the complexities of implementing circular models and achieve sustainable outcomes (Gonçalves et al., 2022). The CI notably contributes to economic progress, but primarily through waste generation. Victar and Waidyasekara (2024) and Wijewansha et al. (2021) highlighted that construction is pivotal in fuelling economic expansion. However, it poses significant environmental challenges due to its intensive use of resources and high waste generation levels. Furthermore, CE is a driven framework for construction material preferences in Sri Lanka, featuring a '10R' hierarchy designed to promote sustainable decision-making. CE selects materials that reduce environmental impacts at every stage of their lifecycle, incorporating strategies such as refusing, reducing, reusing, and recycling. Additionally, it advocates for practices like repurposing, repairing, and remanufacturing, all aimed at enhancing resource efficiency and minimizing waste in CI (Wanaguru et al., 2022). Furthermore, regulatory provisions in the construction industry ensure compliance with environmental legislation, building regulations, and urban planning policies.

The enforcement of regulations in the CI is to minimize pollution, manage waste, and conduct environmental impact assessments governed by regulatory provisions. Regulatory provisions regulate construction activities and enforce laws to prevent environmental degradation. The collective purpose of regulatory provisions is to ensure sustainable development by regulating environmental protection, construction standards, and physical planning to promote safe, efficient, and environmentally responsible construction practices. Given the significant environmental impact of the CI , the CE is recognised as one of the most effective sustainable approaches to mitigating these adverse effects (Stošić & Šmelcerović, 2023). As Benachio et al. (2020) highlighted, the application of CE in the CI helps retain the maximum value of materials. Similarly, CE initiatives aim to minimise resource input and usage (Liu et al., 2022). Implementing CE principles in the CI contributes to waste reduction, resource conservation, and the advancement of sustainability (Hossain et al., 2020). CE practices are significant for the transition towards CE in the CI (Gamage et al., 2024; Guerra et al., 2021; Senaratne et al., 2021). Gamage et al. (2024) emphasise that implementing CE practices in a construction project requires proper planning from the design stage, as early decisions impact subsequent phases. Countries such as the UK, Australia, Germany, and China have already incorporated these considerations into their construction practices (Bleischwitz et al., 2022).

The UK has recently enacted comprehensive measures to embed CE principles in law, notably through the Environment Act 2021 and its regulations implementing the European Union's CE Package (CEP). The UK government is strongly committed to promoting the CE through various laws and regulations. One of the most important CE laws in recent years is the Environment Act 2021, which provides a legal framework for environmental protection and includes provisions for Extended Procedure Responsibility (EPR) schemes. Complementing this, the Producer Responsibility Obligations Regulations place specific requirements on businesses involved in the supply chain. The landfill regulations discourage the disposal of waste in landfills, thus making it more expensive. This law pushes businesses to consider alternatives such as recycling and reusing materials.

In addition to direct legislation, the UK government has introduced initiatives to promote energy efficiency and reduce environmental impact in the CI. The Energy Savings Opportunity Scheme (ESOS) is a mandatory program that requires businesses to conduct regular energy law. These aspects identify energy-saving opportunities, often including strategies to improve resource efficiency and reduce waste. Accordingly, the UK Environment Act 2021 addresses CE practices for the CI. Even though these legal provisions for CE are common in the UK, Laws about CE implementation in Sri Lanka are scarce.

The following legislation are related to CE in the CI in Sri Lanka:

1. National Environmental Act, No. 47 of 1980 and its Amendments
2. Urban Development Authority Law, No. 41 of 1978
3. Coast Conservation Act, No. 57 of 1981
4. Town and Country Planning (Amendment) Act, No.49 of 2000
5. Municipal Councils Ordinance, Urban Councils Ordinance, Pradeshiya Sabhas Act (Local Authority legislation)
6. Construction Industry Development Act, No. 33 of 2014
7. Sustainable Development Act, No. 19 of 2017

The National Environmental Act, No. 47 of 1980, sets the foundation for environmental protection; the Urban Development Authority Law, No. 41 of 1978, focuses on planning and urban growth; the Coast Conservation Act, No. 57 of 1981, addresses coastal management and protection; and the Town and Country Planning (Amendment) Act, No. 49 of 2000, outlines land use and spatial planning. Local Authority Laws (Municipal Councils Ordinance, Urban Councils Ordinance, Pradeshiya Sabhas Act) regulate construction activities through building permits and zoning rules. The Construction Industry Development Act, No. 33 of 2014, governs the standards and development of the construction industry. Keywords such as "construction", "development activities", "waste", "resource efficiency", "waste management", and "waste disposal" were used to find relevant sections in that legislation. These legislations are highly relevant to CE implementation in CI, even though the legislations currently attempt to link with CE implementation in Sri Lanka.

The lack of adoption of law aligned with the CE practices in the Sri Lankan construction sector could result in unsustainable resource consumption (Weerakoon & Thayaparan, 2023), increasing environmental deterioration, resource reduction, and insufficient waste management practices and hindering sustainable development like other countries, as discussed in the above sections. Also no any research has found a relationship between

the CE practices and law within the CI in Sri Lanka, resulting in a significant knowledge gap. Accordingly, to fill this literature gap and the practical need, this study aims to compare the legislation provisions for CE in CI in Sri Lanka and the UK for the better implementation of CE in CI in Sri Lanka with the following three objectives:

- Identify the legislation provisions for CE implementation in CI in the UK and Sri Lankan Jurisdiction.
- Identify the pitfalls of legislation provisions for CE implementation in CI in Sri Lankan Jurisdiction.
- Propose the best practices and their main legal aspects for Sri Lanka.

2. METHODOLOGY

This study begins with a comprehensive literature review to reach findings of the research. It establishes the context of CE practice in the construction industry of Sri Lanka and other countries, and then examines legislation related to CE implementation in CI in the UK and other countries to determine the CE practices with legal aspects used in CI. A desk study tested legislation in the UK and Sri Lanka associated with CE implementation in CI. The UK present contrasting approaches in embedding CE principles in line with English Common Law principles (Castro et al., 2022). The UK has taken a proactive stance, enacting comprehensive legislation related to English Law. Sri Lankan legal system is highly influenced by English Law. Therefore, this study is limited to English Legal System. A robust literature review process strengthens knowledge advancement by integrating insights from various empirical studies and developing a structured theoretical foundation (Kraus et al., 2022). Standalone literature reviews enable researchers to critically assess existing scholarship, uncover gaps, and propose directions for future research (Snyder, 2019). The literature search was conducted across three academic databases: (i) Google Scholar, (ii) Web of Science, and (iii) Scopus. The search strategy targeted key terms such as 'Circular Economy', 'Legislation', 'UK', 'Sri Lanka', and 'construction industry'. Emphasis was placed on peer-reviewed journal articles and conference proceedings published within the last fifteen years to ensure the relevance and currency of the selected literature.

This study adopts a qualitative research approach, which is particularly well-suited for exploring the multifaceted nature of the pitfalls in CE and the legal provisions of CE practices in the Sri Lankan construction industry. Qualitative research is recognised for its capacity to provide rich, contextualized insights, especially when addressing intricate socio-economic and institutional dynamics (Ding et al., 2023; Saunders et al., 2024). The study follows a systematic research process, as illustrated in Figure 1.

The process continues with a comprehensive literature and documentary review to investigate critical aspects such as legislation related to CE implementation in CI in the UK, the pitfalls of legislation in Sri Lanka, and to propose best practices with legal aspects. The findings are analysed using manual content analysis, which is particularly effective for qualitative studies as it facilitates the extraction of meaningful insights while maintaining methodological rigour (Ullah & Ameen, 2018).

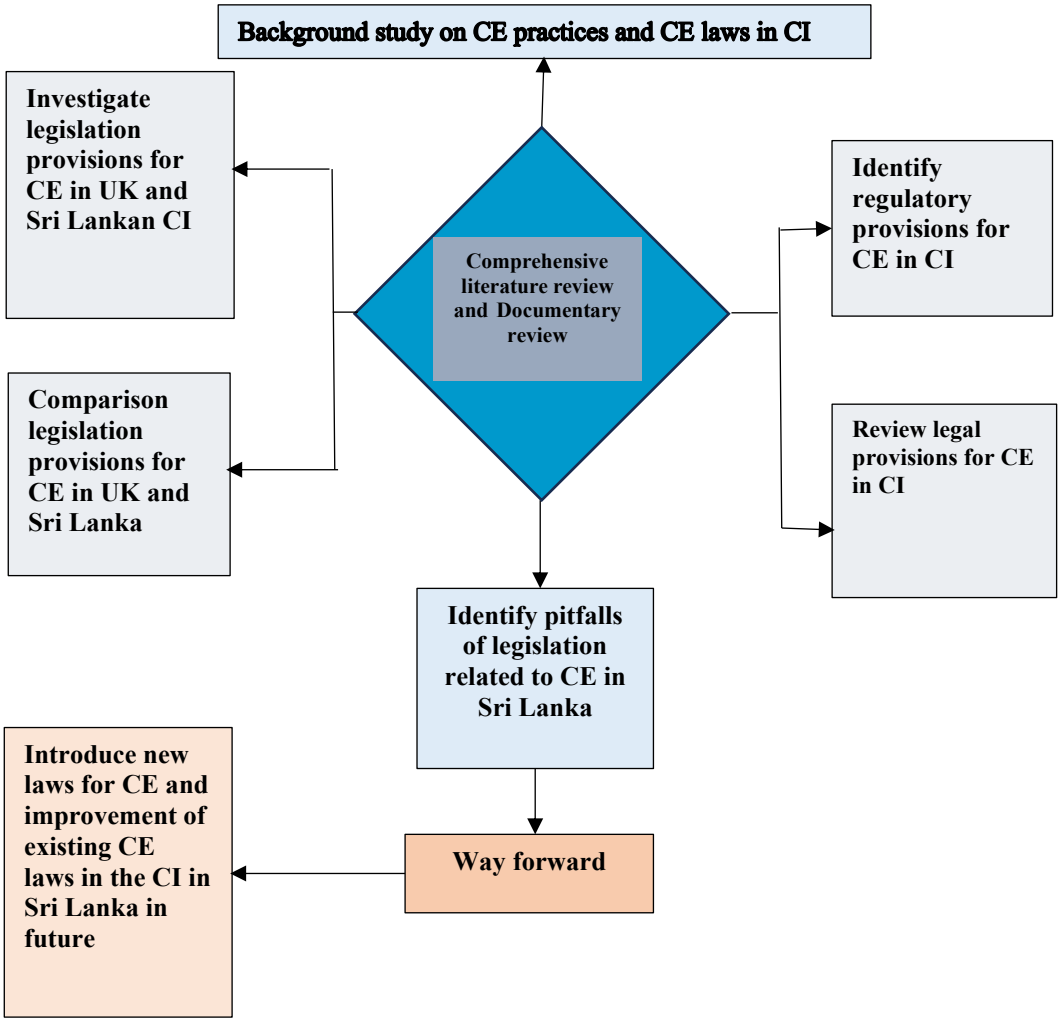

Figure 1 - Research process

3. RESEARCH FINDINGS

This study first identifies the CE and its guidance of Sri Lanka and the UK. This research helps to know about the legal aspects of CE in Sri Lankan and UK CIs. Finally, this research focused on looking into best practices of CE with legal aspects to implement in Sri Lankan CI**.**

3.1 COMPARATIVE OVERVIEW: SRI LANKAN AND UK LEGISLATION IN THE CONTEXT OF CE

The United Kingdom's Environment Act 2021 and Sri Lanka's National Environmental Act No. 47 of 1980 represent two generations of environmental governance. While both legislations target to protect and manage the natural environment, their approaches to resource efficiency, waste reduction, and sustainability. The UK Act is identified as a potential enabler for the CE process, as it helps link environmental goals with CE-driven initiatives. Through this alignment, this Act lays the groundwork for fostering sustainable construction practices across the UK. It introduces waste disposal, waste recovery, and overall waste management methods. This Act provides sustainability for the building,

thus directly affecting the CE principles. Consequently, the UK government's legal approach to CE aspects could be practiced on construction sites.

Table 1 presents a comparative analysis of CE practices and their implementation within the construction industries of the United Kingdom and Sri Lanka. The information has been synthesized from various secondary sources, including government reports, peer-reviewed scholarly articles, and industry publications. The aim is to highlight the key differences between the two countries regarding legislative frameworks, government strategies, industry adoption, and the overall maturity of CE implementation in the construction sector.

Table 1: Comparative analysis of CE practices in the UK and Sri Lanka

Aspect	United Kingdom	Sri Lanka
Legislative Framework	The UK has a strong legislative framework supporting CE, such as the Environment Act 2021 and Waste Regulations (UK Green Building Council, 2021).	Limited legislative support is available for CE in the construction sector in Sri Lanka, with no specific laws or regulations currently in place to mandate CE practices (Wijewickrama et al., 2021).
Government Strategies, Policies, and Law	National strategies such as Construction 2025 and Circular Economy Package guide CE implementation law (UK Green Building Council, 2021).	Sri Lanka lacks a formal strategy focused on adopting to CE in the construction sector (Victar & Waidyasekara, 2024: Wijewickrama et al., 2021).
Implementation Stage of Law for CE	The UK has advanced in integrating CE practices driven by policies, industry incentives, and government initiatives (Victar & Waidyasekara, 2024: Wijewickrama et al., 2021).	CE is still emerging in Sri Lanka, with awareness and implementation primarily voluntary, limited to isolated efforts (Wijewickrama et al., 2021).
Industry Adoption	High adoption of CE practices in the UK construction industry, influenced by policies and industry commitment to sustainability (UK Green Building Council, 2021).	Industry adoption is low in Sri Lanka, with implementing CE practices, due to the absence of a legal framework (Gamage et al., 2024: Wijewickrama et al., 2021)
Awareness of CE principles, law, and its Law	Extensive education and professional development programs are available to support CE practices in construction (UK Green Building Council, 2021)	Awareness in Sri Lanka are limited, focused on Circular Economy principles (Wanaguru et al., 2022; Wijewickrama et al., 2021)
Incentives and Law Enforcement	The UK government provides financial incentives, grants, and compliance monitoring to support CE adoption (UK Green Building Council, 2021).	Minimal financial incentives and weak enforcement of environmental policies in Sri Lanka hinder the widespread adoption of CE practices. (Weerakoon & Thayaparan, 2023; Wijewickrama et al., 2021)

Aspect	United Kingdom	Sri Lanka
Key CE Practices in Use	Common CE practices in the UK include modular construction, material reuse, design for deconstruction, and BIM integration (Ding et al., 2023; Saunders et al., 2024)).	Material reuse and recycling have been implemented in few projects in Sri Lanka, but large-scale adoption of CE practices remains very limited. (Gamage et al., 2024; Guerra et al., 2021; Senaratne et al. 2021)
Environmentally friendly alternatives to the industry	High adoption of CE practices in the UK construction industry. (Kraus et al., 2022).	Integrating CE principles during the early stages of design and planning can significantly enhance sustainability in construction industry by promoting efficient material utilization, minimizing waste (Wanaguru et al., 2022)

In contrast, Sri Lanka's legal framework for CE is fragmented and largely policy-driven. While principles such as waste minimization and recycling are acknowledged in the National Environmental Act and Sustainable Development Act of Sri Lanka, they are not enforced through binding obligations. Recycling and Sustainable construction practices are encouraged by institutions like CIDA, but the lack of regulatory mandates has still prevailed. Overall, Sri Lanka shows interest in CE practices, but the absence of cohesive legislation and enforcement mechanisms hampers progress compared to the UK's more mature and structured approach.

Table 2 presents a comparative analysis of CE practices with their regulatory procedure within the construction industries of the United Kingdom and Sri Lanka.

Table 2: Comparative analysis of CE practices with their regulatory framework and its procedure

Regulatory Aspects and Procedure	UK Environmental Act 2021	Sri Lankan Environmental Act 1980
Legislative Regime and Alignment with CE	Explicitly incorporates CE principles. Included detailed provisions for resource efficiency, waste minimization, extended responsibility and recycling schemes.	Focuses primarily on establishing institutional structures and general environmental protection, without specific reference to circularity, reuse of materials, or life cycle thinking in industrial processes.
Regulatory Institute and Monitoring	Established the Office for Environmental Protection (OEP) to oversee compliance, advise on policy, and enforce environmental standards, including those supporting CE transitions.	Sri Lanka's Central Environmental Authority (CEA) plays a more advisory and administrative role, lacking a dedicated mechanism for policy innovation or enforcement tailored to CE.
Compliance Applications	Strongly addresses manufacturing Tax and Producer Responsibility Obligations; it does not directly tackle construction waste, despite the significant environmental footprint of the sector.	The legislation does not classify between industrial sectors, offering any dedicated policies for construction waste or CE practices within construction and demolition activities.

Regulatory Aspects and Procedure	UK Environmental Act 2021	Sri Lankan Environmental Act 1980
Modern Policy Support Mechanisms	Include economic tools like taxes and deposit schemes to encourage waste prevention and material reuse.	Sri Lanka's Act, while establishing essential foundations such as environmental councils and local agencies, lacks economic instruments or incentives for industries to adopt circular economy practices.
Adaptability of legal framework	UK Act is forward-looking, with requirements for periodic policy reviews, measurable targets, and responsiveness to environmental data. It supports long-term planning aligned with net-zero and sustainability goals.	Sri Lanka's 1980 Act is less adaptable to emerging concepts such as the CE and does not mandate long-term target setting or regular legislative updates.

The United Kingdom and Sri Lanka present contrasting approaches to embedding CE principles into law. The UK has taken a proactive stance, enacting comprehensive legislation like the Environment Act 2021, which mandates practices such as waste minimization, recycling, sustainable design, and extended responsibility (Alhawari et al., 2021). Strong enforcement bodies and a clear policy framework support these legal requirements, positioning the UK as a leader in CE implementation across sectors, including construction. Following UK law that encourages waste reduction and environmental sustainability, the emphasis on CE principles is ingrained from the beginning of projects (UK Green Building Council, 2021).

In contrast, Sri Lanka's legal framework – though built on Acts like the NEA, CIDA, and UDA– remains fragmented and lacks enforceable mandates specific to CE practices. Policies such as the Sustainable Development Act 2017 recognize CE practices but are not backed by clear and binding regulations for the construction sector. This results in inconsistent implementation of CE with legal aspects for CI rather than systemic change.

Despite these gaps, Sri Lanka has opportunities to strengthen its CE transition by learning from a country like the UK. Introducing regulations on construction waste management, promoting reuse and recycling through legal mandates, and improving inter-agency coordination could significantly advance its efforts. Ultimately, aligning the construction law with circular principles is vital for environmental protection, resource efficiency, and long-term sustainable development.

3.2 PITFALLS OF LAWS FOR CE IMPLEMENTATION IN SRI LANKAN CI

Sri Lanka faces significant pitfalls in integrating CE principles into its construction legal framework, especially compared to the UK's more advanced and coordinated system. One of the primary issues is the fragmented legal and institutional structure, where obligations are scattered across multiple bodies without precise coordination and accountability. Unlike the UK, where oversight is streamlined under agencies like the Environment Agency and the Office for Environmental Protection, Sri Lanka lacks a centralized authority for CE initiatives, causing policy gaps and poor enforcement. There are few specific regulations and standards promoting recycling, reuse, or sustainable

construction, contrary to the UK's strict waste separation laws, landfill bans, and economic incentives like landfill taxes. Weak enforcement mechanisms, limited resources for monitoring, and a lack of penalties for illegal dumping further undermine the progress (Alhawari et al., 2021).

Sri Lanka's waste management law and market for recycled construction materials are still underdeveloped, discouraging industry participation. The Sustainable Development Act 2017 could provide a basis for future reforms. Lessons from the UK, such as implementing Extended Producer Responsibility and Mandating Construction Waste Management Plans, could guide Sri Lanka in building a more sustainable and circular construction industry. The legal aspects of CE adoption are particularly crucial, as they provide the enforceability and structure needed for wide-scale implementation. CE practices are unlikely to move beyond pilot initiatives without legal mandates or remain dependent on individual commitment rather than systemic change (Alhawari et al., 2021). The UK's integrated and enforceable legal framework supports CE goals through clear targets, economic incentives, and strong oversight, contrasting with Sri Lanka's less developed legal integration of these CE principles.

3.3 BEST PRACTICES OF CE WITH LEGAL ASPECTS FOR IMPLEMENTATION IN SRI LANKAN CI

The information discussed above provides a comparative analysis of CE practices and legislation provisions in the UK and Sri Lanka. Thereby, the study identifies the pitfalls of the current practices of CE with legal aspects in Sri Lanka. Furthermore, with the critical review CE practices and legislation in the UK, the study identifies what best practices and related legal aspects that are suitable to Sri Lanka to enhance the application of CE in CI as revealed in Table 3.

Table 3: Best practices and its legal aspects with recommendations

Strategy	Recommendations	Legal Aspect	Best practice
Pre-Construction Stage			
Sustainable design and planning	Encourage design professionals to follow CE principles (Velenturf et al., 2019).	Establish regulations mandating that new building projects include a CE evaluation in their environmental impact reports as part of a sustainability evaluation. This can be included in the National Environmental Act's current environmental clearance procedure (1980) (Wijewickrama et al., 2021).	Modify urban development and planning laws and building codes to require circularity, such as flexible and reusable design. `
Circular Procurement Practices	Implement Procurement laws and policies to use circular materials in a circular economy (Castro et al., 2022).	Set up government procurement policies and laws to use the CE practices in government and private sector	Combine the circular economy principles and procurement guidelines to improve the contractors'

Strategy	Recommendations	Legal Aspect	Best practice
		projects (Kraus et al., 2022).	awareness (Wanaguru et al., 2022).
Incentivizing and legalizing Green and Circular Certification	Offer rewards such as certifications, financial benefits, or fast-tracked permitting to developers who integrate CE principles into their project designs through legalization (Alhawari et al., 2021).	Set up a Green Building Certification that includes circular economy standards, similar to LEED, and make it compulsory for planning approval for large projects (Hailemariam & Erdiaw-Kwasie, 2023).	Collaborate with the Sri Lanka Green Building Council (SLGBC) to create a certification that includes circular economy principles in the green building process (Gamage et al., 2024).)
Awareness and Training for legal aspects of CE	Organize training and awareness programs for planners, designers, contractors, and local authorities to highlight the advantages of the CE.	Make CE training mandatory for construction professionals as a requirement to obtain or renew licenses and certifications (Victar & Waidyasekara, 2024).	Collaborate with the professions and industry organizations to provide professional development programs focused on CE basis (Weerakoon & Thayaparan, 2023)
Material Passports and Building Information Modelling (BIM)	Make it mandatory for construction projects to use Material Passports and BIM to track material use, composition, and future reuse or recycling potential at the end of a building's life cycle (Alhawari et al., 2021)	Introduce laws requiring digital documentation of materials using BIM in the planning and approval process and mandate Material Passports for all public and large-scale private construction projects (Hailemariam & Erdiaw-Kwasie, 2023).	Update local building codes to mandate BIM for large projects and create a national Material Passport database to track material data for Sri Lankan construction projects (Wijewickrama et al., 2021).
Post-Construction Stage			
Waste reduction regulations	Implement strict regulations for managing construction and demolition waste and create programs for material segregation, recycling, and reuse during and after construction (Kraus et al., 2022).	Enforce waste management regulations under the National Environmental Act, amending them to include mandatory waste reduction and material reuse targets for construction projects (Alhazmi et al., 2021)	Develop National Construction Management regulations with recycling targets and require contractors to report the amount of waste diverted from landfills (Ding et al., 2023; Saunders et al., 2024)
Material Reuse and Recycling Regulations	Set up systems for collecting, sorting, and recycling construction materials after demolition and promote using reclaimed materials in new	Enforce Extended Producer Responsibility (EPR) laws to hold contractors accountable for the disposal and recycling of construction materials, incentivizing	Introduce regulations requiring contractors to submit detailed plans for material collection and recycling during demolition or refurbishment, integrating this into existing

Strategy	Recommendations	Legal Aspect	Best practice
	projects (Ding et al., 2023; Saunders et al., 2024)	material reuse and promoting a sustainable lifecycle (Kraus et al., 2022).	waste management laws (Wanaguru et al., 2022)
Laws for Building adaptability and lifecycle management	Promote building designs that enable easy adaptation, upgrading, or retrofitting, extending the lifecycle of materials and structures (Alhawari et al., 2021)	Enforce regulations that require building projects to include plans for future adaptability and specify recyclable materials in their designs (Gamage et al., 2024).)	Update building regulations to include requirements for adaptability and lifecycle planning, ensuring developers provide provisions for future reuse or repurposing of the structure (Weerakoon & Thayaparan, 2023)
Post-construction performance monitoring regulations	Establish regulations for continuously monitoring a building's environmental performance, including energy use, waste management, and recyclability (Velenturf et al,2019).	Require Building Performance Evaluation (BPE) reports linked to Green Building Certifications, with regular inspections to ensure compliance with CE practices (Ding et al., 2023; Saunders et al., 2024)	Mandate annual sustainability audits for buildings, focusing on material reuse, energy efficiency, and recycling, supported by frameworks such as the Sri Lanka Sustainable Development Act (Wijewickrama et al., 2021).
Repair and reuse framework	Create frameworks for repairing and reusing building materials and components, promoting maintenance, refurbishment, or adaptation over demolition (Ding et al., 2023; Saunders et al., 2024)	Amend the existing legislation to include repair and reuse guidelines for construction projects, mainly residential and commercial buildings (Wijewickrama et al., 2021).	Establish a repair and reuse code of practice with guidelines for building refurbishment, enforceable through building regulations (Gamage et al., 2024)

In summary, implementing CE practices within Sri Lanka's construction sector holds significant promise for reducing environmental impact, conserving resources, and aligning with global sustainability targets. However, legal reforms must go hand-in-hand with policy innovation and industry collaboration to realize this transformation.

4. CONCLUSIONS AND RECOMMENDATIONS

This study compares the legislation provisions for Circular Economy (CE) in the Construction Industry (CI) in Sri Lanka and the UK to improve the implementation of CE in CI in Sri Lanka. It specifically focuses on integrating the law for CE principles into construction strategies. The aim was to understand the legal framework governing CE implementation and to draw comparisons between Sri Lanka and the United Kingdom. The United Kingdom and Sri Lanka present contrasting approaches in embedding CE principles in line with English common law and their legal system. The UK has taken a proactive stance, enacting comprehensive legislation. In the UK, CE has become a guiding framework for sustainable construction practices, supported by legal and

regulatory mechanisms such as the Environment Act 2021, Building Regulations, and national CE strategies. These regulations aim to minimize construction and demolition waste, encourage the reuse of materials, and set clear guidelines for sustainable design and deconstruction. The UK's legal structure also fosters innovation in materials science, green procurement, and modular construction aligning with CE objectives. On the other hand, the Sri Lankan context reveals institutional and regulatory fragmentation. Environmental impact assessments (EIAs) are legally required for specific projects, but there is no comprehensive legal framework to enforce CE principles across all construction phases. This research underscores the critical role of law in enabling circularity for a proactive, structured, and collaborative approach to embedding CE principles within all phases of the construction lifecycle in Sri Lanka.

Introducing CE laws for construction authorities, regulatory bodies, and educational institutions is necessary to create a unified vision for circularity in construction. These practices are increasingly common in the UK due to strong policy incentives and industry standards. In Sri Lanka, some of these strategies are recognized in theory. However, their practical application is limited, primarily due to cost concerns, lack of technical knowledge, and insufficient legal support.

Sri Lanka is still nascent in adopting CE principles. Although the country faces growing environmental and resource-related challenges, existing construction practices remain linear. The review of Sri Lankan legislation, including the National Environmental Act and the Urban Development Authority Law, proved that a significant gap exists in legislation that directly supports or mandates CE aligned practices in the construction sector. The absence of explicit laws for material recovery, waste segregation, and lifecycle planning further restricts the practical implementation of CE strategies on Sri Lankan construction sites. The study recommends that Sri Lanka look to the UK for direct legal transplants and adaptable CE laws that respect local government and physical planning laws.

Therefore, this study contributes to reforming Sri Lankan laws and introducing CE-specific legal instruments. This could include the development of mandatory laws for material reuse, integrating laws for project approvals, tax laws and incentives for sustainable building practices, and enforcement mechanisms to ensure compliance. Best practices, such as sustainability certifications, circular building codes, and public procurement laws, can be localized through pilot programs, stakeholder consultations, and capacity-building workshops. Expanding legal education in CE and awareness campaigns could equip professionals with the knowledge and skills to apply CE laws effectively within the boundaries of the law. This study only included theoretical conclusions from the literature review; more research incorporating empirical data from interviews is proposed.

COMPARISON OF YOLO ALGORITHMS FOR PPE COMPLIANCE MONITORING AT CONSTRUCTION SITES

S. Sivanraj[1], D.N.L.S. Uduwage[2] and M. Tripathi[3]

ABSTRACT

Safety is a critical concern in the construction industry, where workers are exposed to various hazards that can lead to serious injuries or fatalities. Personal Protective Equipment (PPE) is vital in protecting the workers and increasing their safety. However, ensuring consistent PPE compliance among construction workers remains a challenge. To overcome this challenge, this study developed automated PPE compliance monitoring models through the You Only Look Once (YOLO) object detection algorithm. The variants of YOLO algorithms such as YOLOv8-s, YOLOv9-s, and YOLOv11-s were trained to identify the best performance model to detect and classify the presence of humans and four major PPE items: helmets, high-visibility vests, gloves, and boots. To prevent the overfitting of the models, early stopping with a patience level of 20 epochs was set to the models. The system was externally validated using the construction sites' images to check its applicability to the Sri Lankan context. The efficacy of each model was assessed using performance evaluation matrices such as precision-recall curves, mean Average Precision (mAP@0.5), inference time, and loss function values. The results show that YOLOv9-s outperformed the other models in overall performance even though, it went through the highest number of epochs during training. Future work can explore enhancing the YOLOv9-s model performance by integrating motion detection through IoT devices, allowing for more precise tracking of PPE compliance and reducing false detections of idle or stored PPE. This approach could significantly improve real-time monitoring of PPE compliance for worker safety at construction sites.

Keywords: *Construction; Object Detection; Personal Protective Equipment; Safety; Workers.*

1. INTRODUCTION

Personal Protective Equipment (PPE) compliance is essential in construction sites to mitigate workplace hazards and ensure worker safety since the construction industry is one of the most hazardous sectors, with a high incidence of workplace injuries and fatalities (Ajmani et al., 2024). Construction sites often present hazards including falls, slips, trips, exposure to hazardous materials, operating heavy machinery (Bedi et al., 2021) and working at significant heights (Nadhim et al., 2016). Consequently, hazards caused by these at construction sites can be severe for construction workers. Therefore,

safety regulations mandate the compliance of PPE to mitigate the risks (Muntiyono et al., 2021). PPE compliance refers to the proper use of PPE, which significantly reduces the likelihood of workplace hazards; however, ensuring compliance remains a key challenge (Trubetskov et al., 2023). Despite safety regulations, many workers fail to wear the required PPE, partly due to the inefficiency of site supervision and shortcomings in safety management systems (Wong et al., 2020).

According to Trubetskov et al. (2023), site supervision plays a crucial role in maintaining PPE compliance; however, manual supervision is often inefficient and costly (Raoofi et al., 2024). According to Tian (2023), traditional manual supervision is costly and time-consuming for construction sites, which makes it difficult for supervisors to monitor every worker in real-time, leading to increased workplace risks. As a result, there is a growing demand for automated solutions that can enhance PPE compliance monitoring without the need for constant human involvement.

Recent advancements in deep learning and computer vision provide significant alternatives to manual monitoring. According to Pal & Hsieh (2021), deep learning enables the analysis of complex visual data, improving the accuracy and efficiency of PPE detection. Similarly, Bai et al. (2023) found that automated PPE detection using deep learning ensures more consistent and efficient monitoring. Object detection models, particularly those based on the You Only Look Once (YOLO) architecture, have demonstrated high accuracy and speed in real-time applications within the construction industry (Bai et al., 2023; Lin, 2024; L. Wang et al., 2023)

Although several studies have evaluated the performance of YOLO models in detecting PPE compliance at construction sites, there remains a lack of research focusing on the detection of multiple PPE types using the latest YOLO iterations. This study introduces the PPE detection model using YOLOv11-s algorithm and compares its performance with the models developed using YOLOv8 and YOLOv9 algorithms to determine their effectiveness in the real-time detection of helmets, high-visibility vests, gloves and boots. Each model was trained, tested and validated on construction site images.

2. LITERATURE REVIEW

2.1 SIGNIFICANCE OF SAFETY AND PPE COMPLIANCE

Construction sites inherently pose significant risks due to the nature of activities performed, the wide range of equipment in operation, and the dynamic work environment (Sanni-Anibire et al., 2020). According to recent data on occupational hazards, the construction industry continues to experience disproportionately high levels of workplace incidents. Statistics indicate that in 2022, 22.9% of all fatal accidents within the European region occurred in the construction sector. The construction risks are linked to multiple factors, including working in areas prone to trips and slips, operating heavy machinery (Bedi et al., 2021), working at heights (Nadhim et al., 2016), exposure to hazardous materials (Blaauw & Maina, 2022) and exposure to electrocution. Many of these hazards can be avoided if construction sites adhere to PPE compliance.

PPE compliance refers to the proper use of essential safety equipment such as helmets, high-visibility vests, gloves, and boots. These PPEs play a vital role in protecting workers from the construction site hazards (Al-Bayati et al., 2023). Ensuring compliance is crucial in reducing workplace hazards, yet many construction workers fail to adhere to PPE

requirements. Al-Bayati et al. (2023) identified 16 factors that influence PPE compliance in construction, with supervision being a key determinant in ensuring adherence to safety protocols. To enhance PPE compliance monitoring, effective supervision is necessary. However, in large-scale construction projects, manually monitoring compliance can be often costly, time-consuming, and inefficient (Raoofi et al., 2024). Manual monitoring also introduces challenges such as human error, resource constraints, and the inability to track every worker in real-time (Tian, 2023). Due to these limitations, researchers have explored alternative solutions through computer vision-based systems to improve PPE compliance monitoring.

2.2 AUTOMATED PPE COMPLIANCE MONITORING

The use of computer vision has revolutionised construction site monitoring using real-time object detection (Yang et al., 2024). According to Ahmed et al. (2023), computer vision can be used to automate PPE monitoring and to detect compliant and non-compliant workers in real-time. Several studies have demonstrated the effectiveness of computer vision models in detecting PPE compliance. For instance, Delhi et al. (2020), developed a Convolutional Neural Network (CNN) model to detect the presence of construction helmets and high-visibility vests. Similarly, Ahmed et al. (2023) developed a CNN model to detect helmets of different colours, high-visibility vests and safety boots.

The CNN object detection models are broadly categorised into two major types: (1) one-stage object detection and (2) two-stage object detection. The key distinction between these types lies in their approach to regional proposal generation (García et al., 2021). Two-stage detection models, such as the Region-based Convolutional Neural Network (R-CNN), first generate region proposals before classifying and localising objects (Du et al., 2020). This additional step enhances detection accuracy, making them ideal for tasks that require precise object identification. However, one-stage object detection models such as YOLO directly classify and localise the object with high speed in a single pass (García et al., 2021). This approach significantly improves detection speed, making one-stage models highly suitable for real-time applications where fast inference has a higher priority.

2.3 YOLO MODELS FOR OBJECT DETECTION

YOLO is a single-stage object detection algorithm known for its speed and accuracy in detecting multiple objects. It consists of three major components: (1) backbone, (2) neck and (3) head. According to Mahasin & Dewi (2022), the backbone acts as a feature extractor, the neck is the feature fusion module finally, the head is responsible for the classification and localisation of the object.

The YOLO family has undergone several advancements and has been widely applied for PPE compliance monitoring. Research by Delhi et al. (2020) developed a construction safety helmet and high visibility vest detection model using YOLOv3. Similarly, Velasco & Marasigan (2024) investigated the use of YOLOv7 for PPE compliance detection validating its effectiveness in real-time safety monitoring. Additionally, Guney et al. (2024) conducted a comparative study to evaluate the performance of YOLO-NAS, YOLOv8 and YOLOv9 for PPE compliance monitoring. According to Rasheed & Zarkoosh (2024), YOLOv11 is one of the latest versions of the YOLO family. Each YOLO model has variants tailored to diverse computational and application needs (Kishor, 2024). The variants of YOLOv8, YOLOv9 and YOLOv11 vary from nano to

extra-large allowing users to balance speed, accuracy and computational efficiency. The nano variant models are particularly useful for low-power devices which focus on speed, whereas the extra-large variants are useful for high-performance systems. The small model offers a balance between speed and accuracy which is suitable for medium-scale applications such as real-time PPE compliance monitoring.

2.4 SIGNIFICANCE OF THE STUDY

Studies have shown that manual monitoring of construction sites can be costly, time-consuming and inefficient. The challenges of manual construction site monitoring can be overcome by automated techniques especially by using single-stage object detection models such as YOLO algorithms. There are various advancements in the YOLO family, each consisting of a different capability. Several studies have attempted to use YOLO models for PPE compliance detections (Delhi et al., 2020; Velasco & Marasigan, 2024) and a few have carried out comparisons of YOLO models such as Guney et al. (2024). However, no studies have attempted to compare the latest iterations of YOLO, such as YOLOv11, to assess its performance in terms of PPE compliance detections. Therefore, this study was carried out to determine the best YOLO iteration for PPE compliance monitoring.

3. METHODOLOGY

According to Wang et al. (2025), YOLOv10 is an efficient model designed for general object detection; however, it does not inherently support oriented bounding box detection, limiting its suitability for applications requiring precise object localisation. Therefore, this study used three variants of YOLO algorithms such as YOLOv8-s, YOLOv9-s, and YOLOv11-s to develop three PPE detection models. The models detect humans and four essential PPEs such as helmets, high-visibility vests, gloves and boots. The models were developed on an online platform, and their performance was evaluated and compared based on PR values, mAP, and inference speed.

3.1 DATASET

One of the critical stages in developing a model using the YOLO algorithm is collecting a relevant dataset. In this study, 2,092 images were obtained from an online database called RoboFlow. This online database of images was captured from various construction sites without any specific consideration for the geographical location of the site. Therefore, a previously available dataset was suitable for this study. The same dataset of images was consistently used across training, testing, and validation phases of the model to ensure fair comparison. As such, environmental factors such as lighting conditions, weather, or site-specific occlusions were not varied or controlled. However, all photographs were taken during the day, under natural lighting conditions. The dataset was split into 70% for training, 20% for internal validation, and 10% for testing. Furthermore, custom images from local construction sites were collected to externally validate and assess the applicability of the model to the Sri Lankan projects. To maintain consistency across training, validation, and testing phases, all images were pre-processed to a fixed resolution of 640×640×3 in the Red-Green-Blue (RGB) colour scale.

3.2 MODEL TRAINING

This section outlines the training methodology applied in this study. By maintaining the same training parameters and procedures, the evaluation aimed to identify the most optimal YOLO model for PPE detection without bias from differing training setups.

3.2.1 Hyperparameter

Within YOLO models, hyperparameters play a crucial role in balancing model performance and computational efficiency. Several key hyperparameters were utilised in this study, including batch size, learning rate, momentum, and weight decay.

The dataset images were fed into the model batch-wise, with a batch size of 64 images, allowing for efficient training. The learning rate, which determines how quickly a model learns during training, was set at 0.01. The momentum, which helps to accelerate learning and smooth gradient updates, was set at 0.937. Weight decay, a regularisation technique used to prevent overfitting was set at 0.0005. These hyperparameters are preset within the model but can be fine-tuned for optimisation.

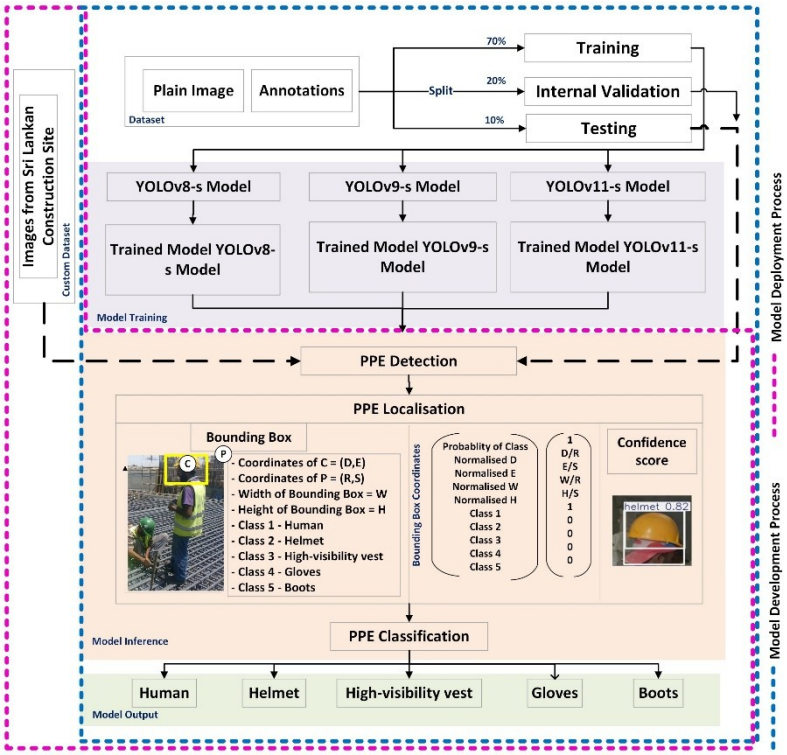

Figure 1: Overall architectural diagram for PPE detection models

Additionally, the number of epochs, which determines how many times the dataset passes through the entire training cycle, was set to 300 epochs in this study. However, prolonged training can lead to overfitting, where the model learns patterns specific to the training data but fails to generalise well to new inputs. To mitigate this, early stopping with patience set to 20 epochs was implemented. This technique prevents overfitting by stopping further training of the model when the model's performance stops improving. The patience value of 20 epochs specifies that the training will automatically stop if there is no improvement in evaluation metrics for 20 consecutive epochs. Accordingly,

YOLOv8-s, YOLOv9-s and YOLOv11-s models went through total epochs of 164, 300 and 160, respectively, during the training and validation process.

3.2.2 Training Process

After splitting the dataset, the three models were trained separately, as shown in Figure 1. The blue dotted line illustrates the model development process, while the pink dotted line represents the model deployment process. In the model development, the training phase utilised two types of input data: (1) plain images and (2) annotations. The annotation provides coordinates of the localised objects such as humans, helmets, high-visibility vests, gloves, and boots. With each training epoch, the system underwent validation. Upon completion of training, the models were further tested to determine and compare the key evaluation matrices. The time to train YOLOv8-s, YOLOv9-s, and YOLOv11-s was 1.273 hours, 3.612 hours and 1.420 hours, respectively.

3.3 MODEL VALIDATION

The validation step in YOLO models is crucial for assessing model performance and generalisation. In this study, the proposed three models underwent two phases of validation: (1) internal validation and (2) external validation. Internal validation was performed using 20% of the dataset from an online database, ensuring that the models were validated in parallel for each training iteration. This process allowed for continuous performance monitoring and determined the optimal number of epochs required for training. By analysing validation results, training was halted at the appropriate stage to prevent overfitting and ensure model generalisation.

Once the models were fully trained and tested, external validation was conducted to evaluate their adaptability to the Sri Lankan context. This phase involved testing the models on custom images collected from Sri Lankan construction sites. These images, captured using mobile phones, provided a diverse and realistic dataset which included various angles, lighting conditions, and image qualities, including both daytime and nighttime scenarios.

3.4 MODEL INFERENCE

Once the models were fully trained, they were tested using 10% of the dataset through the inference pipeline. Model inference refers to the process of using a trained model to predict outputs for an unseen dataset. In the inference pipeline, each model first detected the presence of PPE in the input image. The models then generated bounding boxes with coordinates and confidence scores, allowing them to localise humans and four PPE classes: helmets, high-visibility vests, gloves, and boots. The bounding box coordinates were determined based on key parameters, including the bounding box size, the centre coordinates of the bounding box, and the classes of detected objects within the image with human as class 1, helmet as class 2, high-visibility vest as class 3, gloves as class 4 and boots as class 5.

As illustrated in Figure 1, Point C represents the centre of the bounding box, while Point P denotes the top-right corner of the image. The confidence score associated with each bounding box indicates the model's certainty in detecting the object. While a higher confidence score signifies greater certainty, the detection threshold must be adjusted based on object size to ensure accurate classification. In this study, a confidence threshold

of 25% (or 0.25) was used to balance detection accuracy and false positives. Following localisation, the models classified the detected objects into five classes.

4. RESULTS AND PERFORMANCE EVALUATION

4.1 CONFUSION MATRIX

According to Caelen (2017), a confusion matrix evaluates the performance of classification by a model. It provides the breakdown of the model's prediction against the actual outcomes. When there are six distinct classification categories, a 6×6 confusion matrix can be used to analyse the model's performance. A 2x2 confusion matrix has been given in Table 1.

Table 1: Standard confusion matrix

	Actual Positive	**Actual Negative**
Predicted Positive	True Positive (TP)	False Positive (FP)
Predicted Negative	False Negative (FN)	True Negative (TN)

In the PPE detection models, a true positive would mean correctly detecting a class of Human or PPE, whereas a true negative would indicate correctly recognising the absence of PPE. A false positive would occur if the model mistakenly detected a different class. In the proposed models, there are five primary classes: human, helmet, high-visibility vest, gloves, and boots. These classes represent different PPE components and human presence detected within construction site images. Additionally, when none of these five classes is present in an image, it is labelled as background. During inference, if an image contains no PPE or human presence, it is classified under this background category.

Figures 2, 3, and 4 present the normalised confusion matrices for YOLOv8-s, YOLOv9-s, and YOLOv11-s, respectively. The values have been normalised to ensure comparability across different class distributions. These matrices show the accuracy of true positive classifications, reflecting how well each model classified the presence of different PPE classes. The overall accuracy of each model in correctly classifying PPE items is summarised in Table 2.

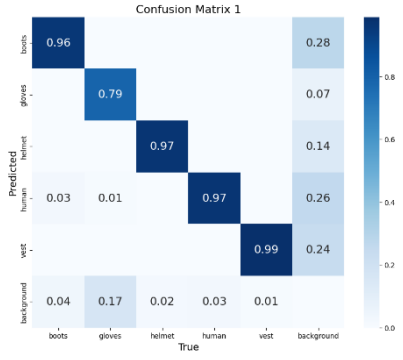

Figure 2: Normalised confusion matrix for YOLOv8-s model

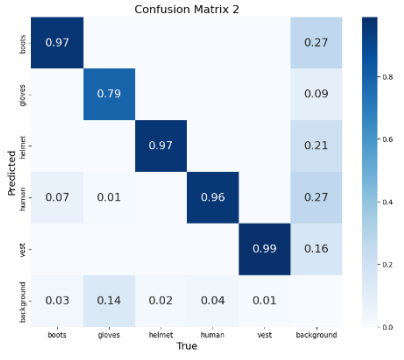

Figure 3: Normalised confusion matrix for YOLOv9-s model

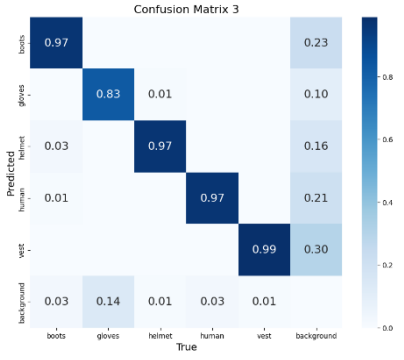

Figure 4: Normalised confusion matrix for YOLOv11-s model

Table 2: Comparison of true positive accuracy of the three models

	YOLOv8-s	YOLOv9-s	YOLOv11-s
Human	0.97	0.96	0.97
Helmet	0.97	0.97	0.97
High-visibility vest	0.99	0.99	0.99
Gloves	0.79	0.79	0.83
Boots	0.96	0.97	0.97

Across all three models, the detection accuracy for humans, helmets, high-visibility vests, and boots remained consistently high, with the high-visibility vest class demonstrating the best performance. However, gloves presented a greater challenge, as all three models exhibited comparatively lower accuracy in detecting them. Instances of misclassification were observed, where images containing no PPE classes were incorrectly classified as containing boots, gloves, helmets, humans, or high-visibility vests. This misclassification occurred across all models, indicating difficulties in distinguishing background elements from actual PPE instances. The highest misclassification rate was recorded in the YOLOv11-s model, where 30% of the misclassified cases involved the incorrect detection of a high-visibility vest in images where none were present, suggesting potential overfitting in the model.

4.2 PRECISION-RECALL CURVE

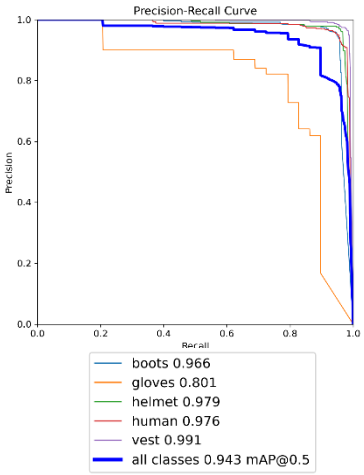

Figure 5: YOLOv8-s PR curve

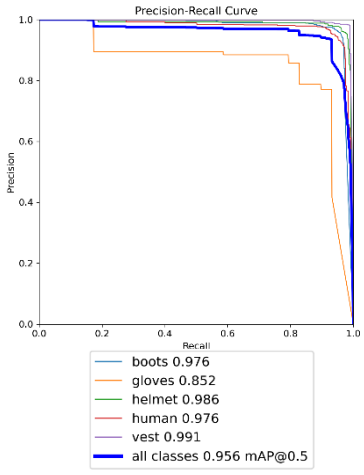

Figure 6: YOLOv9-s PR curve

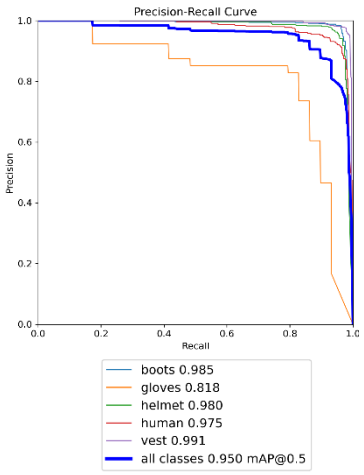

Figure 7: YOLOv11-s PR curve

The models' performance was further tested using precision and recall which are two key metrics for evaluating the performance of the YOLO models. Precision (Equation 1) measures how accurately the model identifies the true positive and shows how often the model is correct when making the classification. Recall (Equation 2), on the other hand, measures the model's ability to detect all relevant instances in a dataset and shows how well a model classifies all the actual classes.

$$Precision = \frac{TP}{TP+FP} \quad Equation\ (1) \qquad Recall = \frac{TP}{TP+FN} \quad Equation\ (2)$$

There is often a trade-off between precision and recall, where improving one may negatively impact the other. A higher precision ensures fewer false positives, while a higher recall reduces false negatives. Therefore, a Precision-Recall (PR) curve was

generated to analyse the trade-off between these two metrics and assess the overall performance of each model.

Figures 5, 6, and 7 present the precision-recall curves for YOLOv8-s, YOLOv9-s, and YOLOv11-s, respectively, in PPE detection. These curves illustrate how well each model maintained a balance between precision and recall. A higher area under the PR curve (AUC-PR) indicates better performance, as it reflects strong classification capabilities. The PR values for YOLOv8-s, YOLOv9-s, and YOLOv11-s models have been summarised in Table 3.

Table 3: Comparison of PR values of the three models

	YOLOv8-s	YOLOv9-s	YOLOv11-s
Human	0.976	0.976	0.975
Helmet	0.979	0.986	0.980
High-visibility vest	0.991	0.991	0.991
Gloves	0.801	0.852	0.818
Boots	0.966	0.976	0.985

Overall, the YOLOv9-s had the highest PR value for 4 out of 5 classes compared to the other two models which had the highest PR values for 2 out of 5 classes. This makes YOLOv9-s the most effective model in terms of precision-recall performance.

4.3 MEAN AVERAGE PRECISION (MAP)

The mAP (Equation 3) measures the average precision at a single Intersection over Union (IoU) threshold, typically set at 50% (mAP@0.5). This provides a single metric that can be used to directly compare the models' performance.

$$mAP@0.5 = \frac{1}{number\ of\ classes\ (n)} \sum_{i=1}^{n.} Average\ Precision \quad Equation\ (3)$$

The mAP scores for YOLOv8-s, YOLOv9-s, and YOLOv11-s were 0.943, 0.956, and 0.950, respectively. These results indicate that YOLOv9-s achieved the highest overall performance, followed closely by YOLOv11-s, while YOLOv8-s had the lowest mAP.

4.4 INFERENCE TIME

The inference time refers to the total time a model takes to process a new unseen image and generate a detection and classification output. A lower inference indicates faster processing, which is crucial for real-time detection applications. The inference times for the three models were 4.4 ms for YOLOv8-s, 7.3 ms for YOLOv9-s, and 5.4 ms for YOLOv11-s. These results indicate that YOLOv8-s is the fastest model, making it the most suitable for real-time PPE detection.

4.5 TRAINING AND VALIDATION LOSS

The YOLO models utilise a unified loss function to evaluate performance and prevent overfitting during training. This loss function consists of three primary components: box loss, classification loss, and distribution focal loss (DFL). The box loss ("box_loss") measures the accuracy of bounding box predictions by evaluating how well the detected object's bounding box aligns with the ground truth. This ensures the precise localisation

of PPE items. The classification loss ("cls_loss") assesses the accuracy of class predictions, determining whether the model correctly identifies PPE categories such as helmets, vests, gloves, and boots. Finally, the distribution Focal Loss ("dfl_loss") enhances refined classification by improving object boundary precision, ensuring that predicted bounding boxes align more accurately with their respective objects.

Figures 8, 9, and 10 illustrate the loss function trends for the three models. As the number of epochs increased, the loss function steadily decreased. Similarly, the precision and recall curves showed a consistent upward trend with increasing epochs. The number of epochs for each model was limited by a patience level of 20 epochs. The training and validation loss values of the three models are summarised in Table 4.

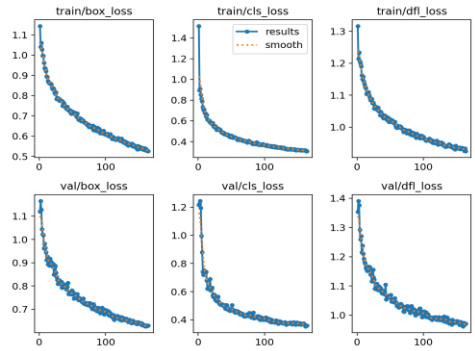

Figure 8: Loss function curve for YOLOv8-s Model for 164 epochs

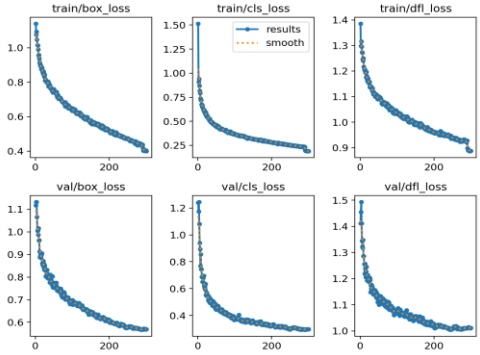

Figure 9: Loss function curve for YOLOv9-s Model for 300 epochs

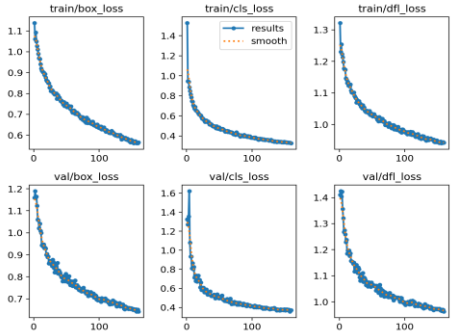

Figure 10: Loss function curve for YOLOv11-s Model for 160 epochs

YOLOv9-s, which was trained for the entire 300 epochs, achieved the lowest box loss, classification loss, and DFL loss among the three models. This suggests that YOLOv9-s had the best bounding box accuracy and classification performance. In contrast, YOLOv8-s and YOLOv11-s were trained for fewer epochs and exhibited higher loss values. The slightly higher loss values in YOLOv8-s and YOLOv11-s suggest they did not reach the same level of optimisation as YOLOv9-s.

Table 4: Comparison of training and validation loss

	YOLOv8-s	**YOLOv9-s**	**YOLOv11-s**
Training Epochs	164	300	160
Box Loss	0.5251	0.3991	0.5654
Classification Loss	0.3071	0.1903	0.3274
DFL Loss	0.9243	0.8883	0.9428

4.6 Overall Comparison of the Models

Table 5 presents the best-performing model among YOLOv8-s, YOLOv9-s, and YOLOv11-s for each performance evaluation metric. The results indicate that YOLOv9-s achieved the highest performance across all metrics, including True Positive Accuracy, PR Value, mAP@0.5 scores, and Training & Validation Loss. However, in terms of Inference Time, YOLOv8-s performed better, demonstrating a faster processing speed.

Table 5: Overall comparison of the model

	YOLOv8-s	YOLOv9-s	YOLOv11-s
True Positive accuracy	✓	✓	✓
PR Value		✓	
mAP@0.5 scores		✓	
Inference Time	✓		
Training and validation loss		✓	

4.7 Model Detections

The detections made by the models are presented in Figures 11 to 16, where each detection is marked with a bounding box and confidence score, indicating the model's level of certainty in its predictions. Comparatively higher confidence scores can be observed for the detections made by YOLOv9-s, indicating its superior performance in identifying PPE with greater certainty. Some inaccuracies were observed in the detections, suggesting areas for improvement. These limitations can be addressed by further training the models using a larger and more diverse dataset to enhance detection accuracy.

Figure 11: Detection by YOLOv8-s

Figure 12: Detection by YOLOv9-s

Figure 13: Detection by YOLOv11-s

Figure 14: Detection by YOLOv8-s

Figure 15: Detection by YOLOv9-s

Figure 16: Detection by YOLOv11-s

5. CONCLUSION AND RECOMMENDATIONS

This study explored object detection for PPE compliance monitoring using YOLOv8-s, YOLOv9-s, and YOLOv11-s models. A dataset from an online database was utilised for training, enabling the models to detect the presence of humans and four essential PPE items, including helmets, high-visibility vests, gloves, and boots. The models were evaluated based on precision-recall performance, mean Average Precision (mAP@0.5), inference time, and loss function analysis to determine their effectiveness in real-time PPE detection. Among the three models, YOLOv9-s demonstrated the best overall performance, achieving the highest mAP@0.5 and the lowest loss values, making it the most optimised for PPE compliance monitoring. However, YOLOv8-s had the fastest inference time. This study contributes to construction safety by identifying an optimal YOLO-based model for PPE detection in construction safety monitoring. However, the model is limited to detecting only helmets, gloves, high-visibility vests, and safety boots, as other essential PPE, such as eye or hearing protection, was not considered. Additionally, factors such as varying lighting and weather conditions were not considered, which may affect generalisability.

While the proposed models effectively detected PPE compliance, future research should focus on enhancing PPE monitoring by incorporating personalised PPE requirements based on specific worker roles rather than relying on generalised detection using YOLOv9-s. Additionally, integrating motion analysis would improve real-time tracking accuracy. This enhancement would also help distinguish actively worn PPE from idle or stored equipment, reducing false detections and improving overall system reliability.

COMPETENCIES OF CONSTRUCTION PROFESSIONALS TO PERFORM CIRCULAR ECONOMY PRACTICES: A SYSTEMATIC REVIEW

D.S.I. Wijayawardena[1], Iresha Gamage[2], Sepani Senaratne[3] and B.A.K.S. Perera[4]

ABSTRACT

The urgent shift towards sustainable construction is not merely a technical endeavour but also a transformation in professional practices. Central to this transformation is the Circular Economy (CE), which champions resource efficiency, design for reuse, and waste minimisation. Despite this, the successful implementation of CE in the construction sector hinges on professionals equipped with the required and evolving competencies. Hence, this research aims to investigate the competencies required by construction professionals to perform CE practices. To achieve this aim, the study synthesises fragmented literature to construct a cohesive and comprehensive understanding of CE competencies of construction professionals. A systematic literature review was conducted using 29 articles, applying the PRISMA framework and the Scopus database, and employing both content and descriptive analyses. The analysis revealed a rich compilation of competencies, clustered into several categories including critical and creative thinking, project coordination and interface, and software and data proficiency. Moreover, it identifies profession-specific competencies for key roles such as project managers, engineers, architects, BIM managers, and quantity surveyors. However, the findings also underscore a considerable gap in both geographic and professional representation, highlighting the marginalisation of certain regions and roles in existing CE literature. Finally, this study offers a common and profession-specific compilation of CE competencies, which can guide academia in curriculum development, inform industry training programs, and support policymakers in designing frameworks to accelerate CE adoption across the built environment.

Keywords: *Competencies; Construction Professionals; Circular Economy (CE).*

1. INTRODUCTION

Amidst the crisis of resource scarcity and the urgent call for sustainability, the Circular Economy (CE) has emerged not merely as a solution but as a transformative vision for the future of industry (Mies & Gold, 2021). As described by the Ellen MacArthur Foundation (EMF), CE is a regenerative and restorative industrial model that embraces both technical and biological cycles (Ellen MacArthur Foundation, 2013). Since its bold entrance in the late 1990s, the CE has been able to infiltrate industries globally, while promoting reuse, recycling, and the extension of product life cycles (Mhatre et al., 2021; Victar et al., 2024). Being responsible for 40% of the total global waste, the adoption of CE strategies in the construction sector is considered essential for creating a more sustainable, resource-efficient, and resilient future (Vergani et al., 2024). Traditional linear waste management practices of generating, collecting, and disposing of waste have significantly contributed to resource depletion, increased greenhouse gas emissions, and environmental degradation (Quashie et al., 2024). To counter these impacts, the CE concept has been introduced to reshape the industry's future (Quashie et al., 2024). Accordingly, the CE-applied construction industry is referred to as ‘circular construction’ (Gamage et al., 2024). Circular construction is a regenerative process that seeks to eliminate unnecessary resource consumption, environmental degradation, and ecological harm (Vergani et al., 2024). Furthermore, Ghisellini et al. (2018) emphasised the importance of embedding circular thinking throughout the construction supply chain. Moreover, with its vast environmental, social, and economic footprint, the construction sector can drive CE forward and create lasting value (Çimen, 2021).

The construction sector today remains fragmented, often hinging on the contributions of individual actors and small enterprises (Bakos & Schiano-Phan, 2021). As Stephan and Athanassiadis (2018) argued, CE becomes attainable only when professionals step forward not just as participants, but as pioneers driven by the motive to create circular construction solutions. Chang and Hsieh (2019) supported this, highlighting the urgent need for professionals who understand value beyond the linear. This transition is not just a technical shift but a profound transformation that hinges on human capability (Victar et al., 2024). Professionals now stand at a crossroads, bearing the weighty responsibility of translating sustainability visions into practical, project-level realities as the circular built environment does not materialise on its own but by those with the courage and competencies to lead it (van Stijn & Gruis, 2020). To rise to this challenge, professionals must be armed with a dynamic portfolio of competencies. According to Kibert (2016), the successful implementation of CE practices demands technical precision, managerial foresight, and entrepreneurial daring. Recent literature, including Bertozzi (2022) highlighted that construction professionals need to bridge knowledge gaps, adopt technical skills, and embrace collaboration to effectively integrate CE principles into their projects. Authors further mentioned that technical competence powers the innovation of circular systems, managerial competence ensures these systems are not just imagined but executed, and entrepreneurial competence fuels the discovery of untapped opportunities that CE unlocks. Despite the growing emphasis on the CE, professionals in the construction industry still lack clarity on the specific competencies needed to implement it effectively (Quashie et al., 2024). Although literature outlines various Competencies for the linear-to-circular transition, translation of this knowledge into practice is still lacking. As a result, the uncertainty among professionals becomes a major barrier, and

CE efforts often fail not due to a lack of ambition but because the professionals lack the competencies to deliver it (Vergani et al., 2024).

To better understand the human capabilities required to drive circular construction forward, it is important to clarify what is meant by "skills" and "competencies." In the literature, the terms have often been used interchangeably. For example, Vergani et al. (2024) referred to them as skills, while others such as Quashie et al. (2024) used the term "competency skills." In contrast, Victar et al. (2024) and Bjerke and Amoudi (2024) emphasised "competencies" as a more comprehensive concept. The term 'competency' itself is rooted in the Latin word competentia, meaning "is authorised to judge" or "has the right to speak" (Caupin et al., 2006), pointing to its deeper connotation of legitimacy and authority in action. In this research, competencies are understood as a blend of knowledge, skills, and capabilities that individuals must possess to effectively carry out their responsibilities (Wong, 2020). Since the majority of reviewed articles refer to them as competencies and professional organisations similarly adopt the term, this study consistently uses the term competencies throughout. The individuals this study focuses on are "construction professionals". The construction industry comprises a workforce and professionals. The workforce comprises skilled and semi-skilled labourers, technicians, support staff, and supervisors whose roles typically do not require advanced professional qualifications (Chan & Kaka, 2007). In contrast, Construction professionals are specialised experts such as architects, surveyors, engineers (civil, mechanical, electrical), quantity surveyors, and other key actors who contribute to decision-making and implementation throughout the construction lifecycle (Vergani et al., 2024). They manage various aspects of a project, including design, structural stability, financial oversight, and resource organisation (UKEssays, 2018).

Despite the growing body of literature on CE competencies in the construction industry, existing studies tend to focus either on general, non-role-specific competencies or on selected professions. Sanggoro et al. (2024) examined how core engineering competencies support CE implementation using Importance-Performance Analysis (IPA) with certified engineers in Indonesia. Dautremont and Gobbo (2025) explored collaborative CE practices across micro, meso, and macro levels in circular construction ecosystems, identifying interlinked activities among all stakeholders. Bjerke and Amoudi (2025) discussed the role of architects in integrating CE principles, while Vergani et al. (2024) emphasised the importance of systems thinking and interdisciplinary collaboration for engineers and architects working towards circularity. Gibbin et al. (2023) highlighted project managers' roles in translating CE goals into project execution strategies through leadership and coordination. Studies, including Victar et al. (2024), addressed quantity surveyors' involvement in recycling and reuse across multiple project stages. Existing research often explores CE from a general or role-specific perspective, but the findings are scattered and lack integration. Without a synthesised understanding of the professional competencies necessary to support circular construction, efforts to embed CE principles into construction practice would be difficult and uninformed. Therefore, this research aims to investigate the competencies required by construction professionals to perform CE practices, achieved through a systematic literature review. The following objectives were addressed.

1. Conduct a descriptive and content analysis of competencies required by construction professionals to perform CE functions.
2. Compare and contrast the competencies required by different professionals

3. Identify the common competencies required by construction professionals to perform CE practices

2. RESEARCH METHODOLOGY

A systematic literature review (SLR) is crucial in construction research to expand knowledge on specific topics (Chen et al., 2022). SLRs offer a transparent, unbiased, and replicable approach to synthesising existing research by following a predefined protocol, enabling comprehensive analysis and evidence-based conclusions that support credibility (Jesson et al., 2011). This study used the Scopus database to locate scholarly articles on competencies required for professionals in circular construction due to its reliability and extensive use in the field, as revealed by Ghaleb et al. (2022). The PRISMA framework was adopted for its clarity, transparency, and structured methodology (Shahruddin & Zairul, 2020). PRISMA integrates the PICO approach to formulate precise research questions (Hosseini et al., 2024), essential for a successful review. To ensure transparency and the rigorous review process, Figure 1 presents the PRISMA flow diagram used to illustrate the systematic screening and selection of literature.

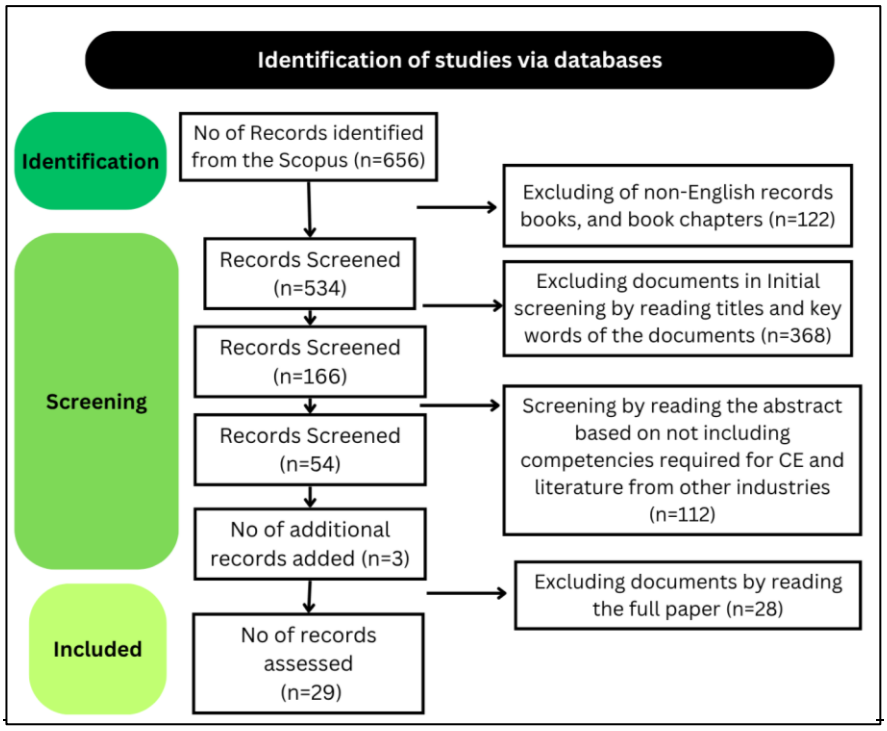

Figure 1:PRISMA flow diagram used for the study

The main search string used to retrieve bibliometric data related to the research area of concern was: ("Circular Economy" OR “Regenerative economy” OR “Zero-waste economy” OR “Cradle-to-cradle” OR “Circular built environment”) AND ("Competenc*" OR "Skill*" OR "Capabilit*" OR "Qualificat*" OR "Expertis*" OR "Knowledg*" OR "Train*") AND (“Construction industry” OR “Construction projects” OR “Construction field” OR “Construction business” OR “Construction sector” OR “Built Environment” OR “Building sector” OR “Quantity Surv*” OR “Project Manag*” OR “Civil Enginee*” OR “Archit*”). Next, the screening process was performed by including journals, conference papers, reviews, etc. Accordingly, 656 articles were selected from the search protocol. Due to language barriers, 11 non-English articles were

excluded. 111 books, book chapters, letters, and notes were excluded as they lack peer review and are prone to becoming outdated.

From the remaining pool of 534 papers, 166 were initially shortlisted based on their titles and keywords. Subsequently, 112 documents were excluded as they were either product-focused or unrelated to the construction sector. Meanwhile, three additional articles were incorporated into the repository after a comprehensive review of their full text, as the title or the abstract did not imply any relevance towards skills, but the full body text did. During the final screening phase, papers that offered limited insight into the CE competency requirements of professionals, or those that focused on occupations only tangentially related to the construction industry, such as real estate agents, were also removed. As depicted in Figure 1, this rigorous process resulted in a final selection of 29 papers. These shortlisted studies were examined through both content analysis and descriptive analysis. The content analysis was used to review the paper's contents thoroughly in broader themes, such as (1) Common competencies required by construction professionals and (2) competencies required by different professionals to perform CE functions. The research findings are presented in the two sections of the 'Findings and Discussion' section.

3. FINDINGS AND DISCUSSION

The findings and discussion section discloses the findings generated by descriptive and content analysis. Content analysis analyses sources in a systematic and objective manner, providing reliable insights that inform action (Mayring, 2021). Meanwhile, descriptive analysis supports identifying trends and variations through a focus on the who, what, where, when, and extent of phenomena (Cote, 2021). This combination provides a comprehensive understanding of the subject researched.

3.1 DESCRIPTIVE ANALYSIS

The publication trend of empirical studies conducted over the past years and the profession-wise distribution of related studies across geographical areas are insights through descriptive analysis.

3.1.1 Publication Trend from 2019 to 2025

The rise of CE principles in construction has increasingly drawn academic attention, particularly in terms of the competencies required for effective implementation. Figure 2 illustrates how scholarly publications on CE-related competencies in the construction sector have evolved over recent years.

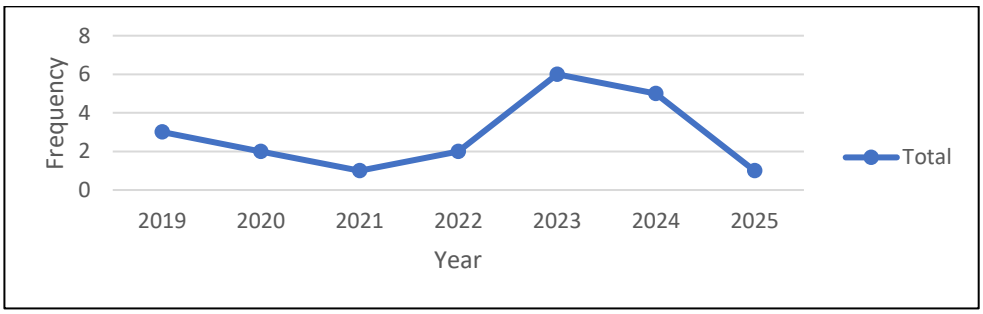

Figure 2: Publication Trend since 2019

The temporal distribution of the reviewed journals reveals a clear upward trend in academic interest surrounding CE competencies within the construction sector. Although the concept of CE began gaining traction globally in the late 1990s, its application to construction professional competencies did not appear in the academic literature until 2019, based on this dataset. This delay could be attributed to the initial focus on establishing a theoretical foundation for CE in construction, while comparatively limited attention was given to identifying and developing the specific competencies required by professionals to effectively implement CE principles. The earliest contributions in 2019 include three publications. This level of output remained relatively modest through 2020 and 2021, representing a formative phase in the discourse. However, a notable increase occurred in 2023, with six publications, followed by five more in 2024. This surge likely reflects a post-pandemic shift in priorities, with increased emphasis on professional competencies, and CE transitions within the built environment. However, the observed reduction in publications for 2025 is due to the SLR being conducted during the first quarter of the year, and publications from the remaining months were not included.

3.1.2 Geographical Distribution

Understanding the geographical origins of research on CE competencies within the construction sector provides vital insights into patterns of global scholarly engagement and regional research priorities. Figure 3 presents the distribution of reviewed publications by country, thereby highlighting both the breadth of international contributions and existing gaps in the current body of literature.

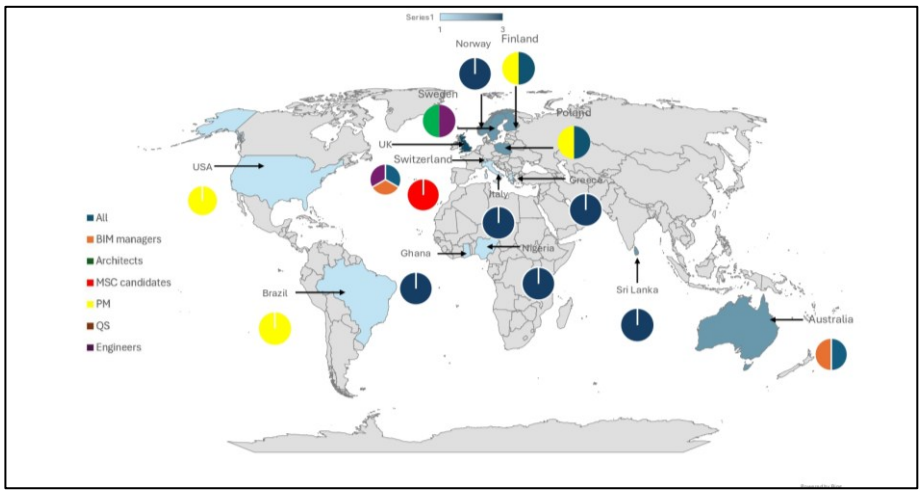

Figure 3: Geographical distribution of publications

The systematic literature review reveals a geographically diverse interest in the competency requirement of construction professionals, with journal articles originating from 17 different countries. As Figure 3 presents, the United Kingdom leads with three publications, covering roles such as engineers, BIM managers, and general CE practices, suggesting a strong national focus on sustainable construction leadership. Countries like Finland, Poland, and Norway follow closely with two studies each, demonstrating notable contributions from Europe. A promising aspect of the review is the inclusion of developing countries such as Nigeria, Ghana, Sri Lanka, and Brazil, each contributing at least one study. These contributions align well with the findings of Quashie et al. (2024), which emphasised the relevance of CE principles in contexts where rapid urbanisation, waste management challenges, and the need for resource efficiency are becoming

increasingly critical. However, the relative lack of representation from Asia and the Middle East points to gaps in the global dialogue that future research could address.

Figure 3 further demonstrates a variety of construction professionals, emphasising that CE adoption requires cross-disciplinary engagement identified during the SLR. Project managers appeared most frequently, with four studies focused on their role in enabling CE through project planning, procurement strategies, and lifecycle thinking. Engineers, while only represented in a few studies, are recognised for their technical contribution. BIM managers appeared in 2 articles from England and Australia, signalling growing attention to how digital tools like Building Information Modelling can support CE decision-making. Quantity Surveyors (QS), represented by two studies from Sri Lanka, highlighted the role and competencies of a QS in the 3R concept-infused CE. One unique entry involves MSc candidates in Switzerland, indicating that CE competencies are increasingly being embedded in academic curricula. Over half of the studies do not focus on a specific role, instead addressing the broader spectrum of CE competencies required by professionals across the construction sector.

3.2 CONTENT ANALYSIS

The CE competencies of construction professionals in a common context as well as profession-specific competencies have been discussed in the content analysis.

3.2.1 CE Competencies

The successful implementation of CE practices in construction demands a profession-specific understanding of relevant competencies. Table 1 below provides a synthesised overview of competencies mapped to key construction roles, reflecting the differentiated yet complementary contributions of each profession toward circularity.

Table 1: Circular economy competencies for construction professionals

Competency	Relevant Profession	Sources
Critical & Creative Thinking: Critical thinking, Creative thinking, Creativity, Foresighted/anticipatory thinking, Positive thinking	Common	3,6,7,8
Problem Solving and Structuring: Complex problem-solving, Problem-solving, Problem structuring, Troubleshooting operational errors	Common	3,5,6,7,8
Decision Making and Judgement: Decision making, Judgment and decision making, Originality judgment	Common	5,6,7
Numeracy and Mathematical Reasoning: Numeracy, Mathematics, Mathematical reasoning	Common	6,7
Analytical and Hypothesis Testing: Analytical thinking, Hypothesis testing, Predictive analysis, Quality control analysis	Common	6,8
Communication: Communication, Effective Communication, Speaking, Active listening, Reading comprehension	Common	3,6,7
Negotiation and Persuasion: Negotiation, Persuasion, Relationship competency	Common	5,6,7
Teamwork and Collaboration: Teamwork, Collaboration, Understanding team dynamism, Interpersonal competence	Common	3,5,6,7,8

Competency	Relevant Profession	Sources
Cultural and Social Awareness: Cultural intelligence, Addressing generational differences, Social perceptiveness, Social awareness	Common	1,6,7
Leadership and Direction: Leadership, Leadership competency, Provision of direction to inspire others, Developing teams, Transforming followers into leaders, Empowering others, Resilience	Common	3,4,6,8
Project Coordination and Interface: Effective coordination and integration of stakeholders, Interface management, Coordination, Operations analysis	Common	2,4,6,7
Resource and Process Management: Management of financial/material/personnel resources, Process management, Material Logistic Plan Implementation, connecting reverse logistics with users, Upcycling	Common	3,6,7
Equipment and Site Management: Equipment maintenance, Operation monitoring, Operation and control, Installation, Repairing, Equipment selection	Common	6,7
Onsite Execution and Practical Competencies: Onsite practical skills, Specification writing, Using suitable structural systems/materials, Suitable site characteristics, understanding wear, value perception, and engineering use	Common	1,3,4,8
Self and Stress Management: Stress management, Self-confidence / Self-control, Resilience, Positive thinking;	Common	6
Empathy and Caring: Empathy, Caring, Humanity, Emotional reasoning, Interpersonal sensitivity	Common	6,8
Adaptability and Flexibility: Adaptability, Adaptability competencies, Cognitive flexibility	Common	6
Curiosity and Active Learning: Curiosity, Active Learning, Learning Strategies, Understanding factors affecting user experience.	Common	6,7,8
Ethical and Entrepreneurial Mindset: Ethical competencies, Entrepreneurship competencies, Service orientation, circular business model integration	Common	3,6,8
Design for Circularity: Eco-design, designing for multiple-use cycles, lean design and construction, cradle-to-cradle principles, built environment restoration, water-sensitive and wetland design.	Common	1,9
Impact Assessment: Sustainability assessment and benefits, rating systems and certification, CE social impacts, environmental assessment methods, social life cycle assessment, circular impact assessment, circular scope definition	Common	1,9
Waste Minimisation: Waste efficient procurement knowledge, Ability to manage waste, Ability to create and implement waste management plan, Personnel commitment to pursuing a solution to waste minimisation, Waste avoidance cost accounting	Common	1,3,6,8
Programming and Tech Design: Technology design, Programming, Technology Design and Programming	Common	6,7

Competency	Relevant Profession	Sources
Software and Data Competencies: Software competencies, Competencies for specific tools, Data analytics, Data management competencies	Common	6
Cybersecurity and Digital Identity: Computer security, Digital identity, Digital rights, Digital Security	Common	6
Digital Fluency and Leadership: Digital literacy, Digital communication, Digital use, Digital strategy, Digital leadership, Digital emotional intelligence	Common	6
Systems Thinking and Evaluation: System thinking, Systems analysis, Systems Evaluation	Common	1, 6, 7
Specialised Quantity Surveying Competencies: risk management, procurement advice, resource management, cost control, cost planning, feasibility studies, value engineering, cost estimation, Life cycle cost analysis, cost-benefit analysis, data standardisation and modelling, embodied ecology costing, and sustainability advisory.	Quantity Surveyor	13
Specialised Architecture, Engineering, and Construction Competencies: 3D printing in construction, technical and geographic insight, CE challenges in real estate, urban mining, energy minimisation and monitoring, aquifer storage and water quality issues, Madaster vision for material passports, non-renewable tech and energy trade, functional and physicochemical building blocks.	Engineers, Architects	9
BIM-Integrated Competencies: 3D modeling, Digitalisation, Quantity takeoff and phase planning, Standardisation and flexibility, Asset and component maintenance, Use visual models to reduce rework, BIM interoperability for waste management, Auto-capture design parameters, Extract waste data from design models, BIM for lifecycle waste management, Use BIM for construction waste analysis, Specify materials from models to reduce variation, Extract material quantities from models, Volumetric modular design application, Integrate construction sequencing early, Modular construction techniques,	BIM Managers	10,11

Sources - (1-Quashie et al., 2024; 2- Hendrianto et al., 2024; 3- Botchway, et al.,2023; 4- Wuni & Shen, 2022; 5-Harala et al., 2023; 6- Siriwardhana & Moehler, 2023; 7- Burger et al., 2019; 8-Górecki,2019; 9- Vergani, et al., 2024; 10-Bjerke & Amoudi, 2024; 11-Ganiyu et al., 2020; 12-Wrase et al., 2023; 13-Victar et al., 2024; 14-Jääskä 2021)

Quashie et al. (2024) identified the competencies driving circularity in the construction industry within developing economies, emphasising the unique, context-specific skills needed in low- to middle-income countries. Drawing from such diverse insights, Table 1 was developed through a structured synthesis of original competencies from multiple sources, categorised into 30 thematic groups such as critical and creative thinking, project coordination, BIM-integrated competencies, and software and data proficiency. While some categories are profession-specific, most are broadly applicable across construction roles. These competencies include skills essential for addressing complex sustainability challenges, supporting stakeholder engagement, and integrating circular principles in projects. Additionally, digital literacy, programming, and data proficiency reflect the

industry's shift toward technology-driven solutions. Competencies, including design for circularity, impact assessment, and systems thinking are key to embedding circular economy principles in construction practices.

3.2.2 Profession-Specific Competencies

Table 1 presents a diverse range of competencies tailored to key professional roles within the circular construction industry. Górecki (2019) emphasised leadership, emotional reasoning, operational analysis, and interpersonal sensitivity as critical competencies for Project Managers to make sustainable decisions, while Jääskä (2021) highlighted collaboration, decision-making, and problem-solving. Vergani et al. (2024) contributed technical and sustainability-related competencies for Architects and Engineers, including 3D printing as well as technical and geographic insight. Bjerke and Amoudi (2024) identified BIM-related skills such as digital modelling, standardisation, and phase planning that support waste minimisation and adaptability. Ganiyu et al. (2020) further explored BIM's role in waste analysis, modular construction, and logistics optimisation. Wrase et al. (2023) proposed a holistic framework of governance, ethics, and digital transformation to prepare CE-ready graduates. Victar et al. (2024) mapped Quantity Surveyors' roles to the 3R (Reduce, Reuse, Recycle) principles, highlighting competencies like life cycle costing and value engineering.

Accordingly, role-specific competencies vary significantly depending on professional focus. Quantity Surveyors, for instance, are primarily concerned with financial and resource efficiency, possessing advanced capabilities in procurement advice, cost control, life cycle cost analysis, and sustainability-related costing methods (Victar et al., 2024). In addition, certain common competencies such as impact assessment align more closely with Quantity Surveyors, given their involvement in project feasibility evaluations and life cycle cost analysis (Senaratne et al., 2024). Meanwhile, BIM managers demonstrate distinct digital fluency, with competencies in 3D modelling, modular construction, lifecycle waste analysis, and integrating digital tools like BIM for circular design and waste reduction (Bjerke & Amoudi, 2024). These variations demonstrate how each profession supports circular economy goals from different angles, reinforcing the need for role-specific competency frameworks tailored to their functions within the construction ecosystem. However, although these studies present profession-specific competencies, the majority of the identified competencies remain relatively general rather than deeply profession-specific, highlighting a notable gap in the existing literature.

3.2.3 Paving the Way Forward for CE Implementation by Construction Professionals

Despite increased academic attention, existing literature still lacks a holistic understanding of how competencies are distributed across different professions and global contexts. One of the most critical gaps lies in the limited focus on specific construction professions. For instance, PMs were the most frequently examined profession, appearing in only five out of twenty-seven studies despite the availability of a few existing research on professions such as Engineers, Architects, QSs, and BIM managers (Górecki, 2019; Victar et al., 2024; Ganiyu et al., 2020). However, key contributors to on-site performance, including site supervisors, MEP engineers, planning engineers, draftsmen, and construction foremen, remain largely unaddressed. Moreover, most of the studies that attempted to identify competencies remain relatively general, indicating a significant gap in deeply profession-specific competency mapping within the

current CE literature. If such detailed mappings were available, the construction industry would be better positioned to maximise the benefits of CE practices by aligning skills development precisely with practical implementation needs. There are also notable geographical imbalances in research coverage. Most contributions originate from European nations such as the United Kingdom, Finland, and Poland (Burger et al., 2019). Most contributions originate from the United Kingdom accounting for three publications focused on engineers, BIM managers, and general CE practices while regions experiencing rapid urban growth, including Southeast Asia, the Middle East, Africa, and Latin America, receive little to no representation. As emphasised by Quashie et al. (2024), these regions encounter unique challenges such as informal labour structures, limited training access, and regulatory fragmentation. Addressing such realities requires context-specific competency frameworks that align with local needs and priorities. Moving forward, there is a need to expand profession-specific studies to include the full range of construction roles involved in circular construction. Additionally, future research should be more geographically inclusive, with a particular emphasis on underrepresented regions where CE adoption can deliver the most transformative impact. Only through such comprehensive efforts can the construction industry be truly equipped to support the global transition to a circular and sustainable built environment.

4. CONCLUSIONS AND RECOMMENDATIONS

This study provided a structured synthesis of the competencies required by construction professionals to implement CE practices, using a systematic literature review approach. It identified common competencies and mapped role-specific competencies across various professions within the sector. Despite the growing academic interest, the current literature remains limited in geographic and professional scope, underscoring the need for a more inclusive understanding of CE competencies in construction. To advance the implementation of CE in the built environment, the following recommendations are proposed. (1) Expand research coverage to include underrepresented regions such as Southeast Asia, the Middle East, and parts of Africa and Latin America, where the built environment is growing rapidly, (2) Conduct profession-specific studies to identify detailed competency frameworks for a broader range of construction roles (3) Promote interdisciplinary education and training programs that align with the identified competency categories, ensuring professionals are prepared for practical CE challenges.

This study contributes to the growing CE literature in construction by identifying both common and profession-specific competencies needed for CE transitions. It presents competencies such as systems thinking, digital fluency, and design for circularity while mapping competencies for key roles, including PMs, QSs, and BIM managers. The research also highlights regional and professional gaps, where most identified skills are general rather than CE specific, with limited representation from countries like China and India, and roles such as site supervisors. These findings guide future, more inclusive CE competency research. However, the analysis was based solely on secondary data, without field-level validation from industry practitioners. Nevertheless, the study systematically synthesises fragmented literature to construct a cohesive and comprehensive understanding of the competencies required by construction professionals to implement CE practices effectively.

COMPETENCY REQUIREMENT FOR PROFESSIONALS INVOLVED IN PUBLIC CONSTRUCTION PROCUREMENT PROCESS: A REVIEW

S.S. Weerathunge[1] and K.A.T.O. Ranadewa[2]

ABSTRACT

Due to its complexity and a series of interdependent activities, public construction procurement (PCP) is often prone to problems such as cost overruns, time overruns, quality compromises and fraud and corruption. These problems ultimately lead to disputes challenging value for money (VFM), which is anticipated particularly in public construction projects. The success of public construction projects ensures VFM, and it is heavily dependent on the competencies of professionals involved in the procurement process. It was revealed that limited research has been conducted, shedding light upon the competencies required by the professionals in the procurement team specifically for the public construction procurement process. Therefore, the research aimed to explore competencies required by professionals, such as Quantity Surveyors, Engineers, and Architects, who are engaged in the procurement team in the public construction procurement process. The research is conducted with a particular focus on laying the foundation to explore these competencies to overcome the identified problems. Accordingly, a comprehensive literature review was conducted. The findings revealed 14 problems in the public procurement process (PPP), and the competencies expected from the leading professionals in the procurement team, including Engineers, Architects, and Quantity Surveyors, were detailed and analysed according to the competency requirements of the selected professional institutes. The findings suggest that procurement professionals must possess a robust understanding of legal, financial, and technical aspects, alongside strong communication and negotiation skills, to navigate the complexities of public construction procurement. The findings of this research will contribute to minimising disputes and improving the efficiency of public construction procurement processes.

Keywords: *Competencies; Disputes; Procurement Team; Public Construction Procurement; Sustainability.*

1. INTRODUCTION

The construction industry is a key contributor to the national economy of any country (Oguntona & Aigbavboa, 2020). Construction procurement plays a crucial role in achieving project goals and defines the structure of responsibilities among participants

[1] Chartered Quantity Surveyor, Central Engineering Consultancy Bureau, Sri Lanka, sasankaweerathunge@gmail.com
[2] Senior Lecturer, Department of Building Economics, University of Moratuwa, Sri Lanka, tharushar@uom.lk

(Gajaman et al., 2019). Within the construction industry, PCP accounts for a substantial proportion of the national economy, leveraging public investment, infrastructure facilities and enabling employment while guaranteeing VFM (National Procurement Commission [NPC], 2024; Uduwage-Don et al., 2024). However, due to its inherent complexity, public procurement is often prone to problems such as additional costs, delays and poor quality, which can escalate into disputes, consuming a substantial amount of money and time (Dita et al., 2020). Therefore, avoiding conflicts at the outset is advantageous, as effectively addressing the problems can prevent them from escalating into disputes (Mitkus & Mitkus, 2014; Gajaman et al., 2019).

Since the construction procurement is a structure which represents a shared responsibility among the parties, problems can be addressed effectively, and successful execution of procurement activities in the right manner is ensured when the professionals possess the requisite expertise (Gajaman et al., 2019; Shehu et al., 2019). Similarly, Komakech (2016) emphasised that, given the complexity and risks involved in public procurement today, the procurement team should possess specific competencies to perform efficiently, maximise VFM, and reduce corruption. The study focuses on Architects, Quantity Surveyors, and Engineers, as they are the key professionals directly involved in pre-contract activities and are formally recognised in relevant institutional competency frameworks (Construction Industry Development Act, 2014).

Effective public procurement is essential for good public services and good government. Since the government spends money on behalf of taxpayers, it is essential for the government to apply the highest professional standards (Publications Office of the European Union, 2020). Therefore, in order to ensure meeting the required quality of the public needs, the public procurement workforce is required to undergo professionalisation (Publications Office of the European Union, 2020).

Problems in the PPP can lead to disputes in the post-contract stage if the problems are not effectively addressed. Poor quality performance, cost overrun, risk overrun, deliverables not fit for purpose, lack of communication, fraud and corruption, and shortage of highly qualified and motivated professionals are some of the problems that ultimately result in disputes (Asiedu et al., 2021; Gunawardana et al., 2021; Uduwage-Don et al., 2024; Ayopo et al., 2016; Naude, 2017; Adhikari, 2015; Construction Industry Development Act, 2014). Therefore, to minimise and avoid disputes, the client needs to obtain services from a professionally well-trained staff of procurement professionals to address these problems. When appointing the procurement team, clients must have a thorough understanding of the required competencies essential for successful PCP.

Even though studies have been conducted on knowledge requirements for the procurement process (Shehu et al., 2019; Komakech, 2016), competencies for Quantity Surveyors (Chamikara et al., 2020; Yogeshwaran et al., 2018), and construction project managers (Moyo & Chigara, 2023) as well as for dispute management (Rajapakshe, 2019), limited research has focused on the competencies required by the professionals in the procurement team specifically in PCP. Thus, there is a need to fill this knowledge gap by comprehensively investigating and synthesising the required competencies of the procurement team involved in PCP based on the existing literature, which primarily focuses on individual professionals. Therefore, this paper aimed to review the competencies required by Architects, Engineers and Quantity Surveyors for the PCP process. The objectives of the research are to analyse the problems in PPP and to

investigate the competencies required by the professionals in the procurement team of public construction projects.

This paper initiates with an introduction followed by the research methodology, the research findings, discussion, contribution of the research and conclusion with recommendations.

2. RESEARCH METHODOLOGY

Research methodology is identified as a series of steps followed by a researcher with the aim of solving a research problem in a logical manner (Kumar & Praveenkumar, 2025). A literature review represents an organised, transparent and replicable process for existing literature (Snyder, 2019). In order to ensure the quality and credibility of the literature review, it is essential to scrutinise high-quality sources such as journal articles, books, and conference proceedings with proper citations (Xiao & Watson, 2019). Therefore, this research relied on journal articles, books, and conference papers to guarantee the reliability and academic consistency of its findings.

Accordingly, this study adopted a comprehensive literature review approach to explore the updated and structured overview of the existing body of knowledge on competency requirements for professionals involved in PCP (Pautasso, 2019). In order to ensure the quality of the review, relevant articles were identified through databases confining to Scopus, ScienceDirect, and Google Scholar using keywords including "competency requirements," "construction procurement," "public construction projects," and "professional competencies in construction". The search was limited to publications from 2001 to 2025 and restricted to English language sources. Studies were included if they discussed competencies in the context of construction procurement, particularly within public sector projects. Non-peer-reviewed articles, non-English studies, and studies unrelated to construction were excluded.

Likewise, a comprehensive literature review was carried out to achieve the aim and objectives of the study by using well accepted academic databases, as noted above, and filtering a sufficient number of relevant research publications through keyword searches while excluding outdated studies. A background study and comprehensive literature review were conducted to examine the PPP, its problems, and competency requirements expected by the Engineers, Quantity Surveyors and Architects. Moreover, the findings were also extended to include the literature from the sources of professional institutions. The study is not limited to the Sri Lankan context and global contexts were considered.

3. RESEARCH FINDINGS

3.1 PUBLIC CONSTRUCTION PROJECTS

Public construction projects are often funded through taxes or government loans and are typically managed by government agencies or private contractors (Delmon, 2017). They are essential to infrastructure development, covering a wide range of sectors such as transportation, education, and healthcare (United Nations Development Programme, 2017). Additionally, these projects contribute to the achievement of sustainable development goals by promoting social, economic, and environmental sustainability (Uenk & Telgen, 2019). Overall, public construction projects play a crucial role in shaping the built environment and fostering economic growth and advancement. They

require careful planning, management, and funding to ensure that they meet the needs of communities and provide lasting benefits for years to come (Uenk & Telgen, 2019).

3.2 PUBLIC PROCUREMENT PROCESS

3.2.1 Public Procurement

Public procurement involves acquiring significant inputs for public investments through the most appropriate means of public funds or external funds and guided by the core principle of VFM (National Procurement Commission [NPC], 2024). PCP is a subset of public procurement which refers to the process by which public bodies acquire goods, services, or works from selected suppliers, from routine goods to large-scale contracts for infrastructure projects (Office of Government Procurement, 2019). Public procurement is now recognised as a profession that plays a key role in the effective management of public resources (Ambe & Badenhorst-Weiss, 2012). PCP plays a vital role in infrastructure development and significantly contributes to the national economy, especially in developing countries like Sri Lanka (Uduwage-Don et al., 2024; Central Bank of Sri Lanka [CBSL], 2014).

3.2.2 Procurement Process

The construction procurement process is a complex process that involves several stages and is essential for establishing and managing contracts (Diófási-Kovács & Tátrai, 2025). There are various construction procurement methods, such as Traditional, Design and Build, Management Contracting, Construction Management, Partnering, Public Private Partnerships, Private Finance Initiatives, and Collaborative Agreements that are selected based on the client's specific project requirements (Osifo, 2024). This research is focused on the procurement process based on the traditional procurement system.

Successful construction procurement depends on aligning each activity within the procurement process with professionals who possess the necessary competencies (Shehu et al., 2019). Further to the author, by performing duties and tasks in an appropriate manner, problems can be avoided beforehand without escalating them into conflicts and finally into disputes.

3.3 PROBLEMS IN PUBLIC PROCUREMENT PROCESS

PPPs are susceptible to problems that diminish VFM, erode public trust, delay project delivery, and compromise quality, affecting successful completion (World Bank, 2018). These problems and poor procurement practices can be identified as the prominent causes for hampering the economic growth of a country (Delmon, 2017; Raymond, 2008). Irrespective of whether a country is developed or developing, problems are prevalent in the PPP. The following Table 1 outlines problems in the PPP in the construction industry.

Table 1: Problems in public procurement process

Problem No.	Problem in the public procurement process	Authors
P-01	Cost overrun	1, 12, 15, 25, 26
P-02	Time overrun and delays in project implementation	1, 12, 15, 22, 25
P-03	Poor quality performance	6, 9, 10, 11, 20, 22, 24, 25, 26

Problem No.	Problem in the public procurement process	Authors
P-04	Deliverables not fit for purpose	3, 4, 8, 9, 13, 14, 25
P-05	Inadequate social and environmental cost valuation	4, 8, 25
P-06	Lack of communication	2, 15, 5
P-07	Risk Management Failures (Risk Overrun)	1, 12, 15, 25
P-08	Outdated Technology	6, 9, 10, 11, 25
P-10	Inadequate VFM assessment	6, 7, 9, 25
P-11	Shortage of highly qualified and motivated professionals	28, 17
P-12	Biased award procedures	27
P-13	Price inflation and overcharging	24
P-14	Recalling the tendering process	19

1.Dubois and Gadde (2002), 2. Chartered Institute of Building (CIOB, 2010), 3. Jones (2007), 4. Organisation for Economic Cooperation and Development [OECD] (2007), 5. Raymond (2008), 6. Walker and Brammer (2009), 7. Dawson et al. (2011), 8. Ameyaw et al. (2012), 9. World Bank (2023), 10. Amemba et al. (2013), 11. Adhikari (2015), 12. Decarolis and Palumbo (2015), 13. Ogunsanya et al. (2019), 14. Naude (2017), 15. Gyawali et al. (2018), 17. Chigudu (2014), 18. Musanzikwa (2013) 19. Uduwage-Don (2024) 20. Dinar & Zayed (2012) 21. Jones (2007) 22. Asiedu et al. (2021), 23. Chimwani et al. (2014) 24. Dinar and Zayed (2012) 25. Gunawardana et al. (2021), 26. Weisheng et al. (2013), 27. Jaafar and Radzi (2013), 28. Ofori (2007)

According to Sinha (2018), common problems in public construction projects include delayed project delivery, poor project planning, cost overruns, poor quality, corruption, safety concerns, inadequate project management skills, and lack of stakeholder engagement (Sinha, 2018). Lack of communication has been identified as one of the major problems in procurement through a survey conducted in the United Kingdom (CIOB, 2010). Among the problems shortage of highly qualified and motivated professionals in public procurement is responsible for the low reputation and undervaluing of public procurement (Ofori, 2007). Jaafar and Radzi (2013) stated that the problems originate with the industry players, who often possess insufficient knowledge of the procurement process. Conversely, disputes in public construction projects frequently arise from various procurement problems within the procurement process itself.

Similarly, disputes can significantly affect construction projects, leading to problems such as project delays, cost overruns, reputational damage and strained relationships among stakeholders (Alaloul et al., 2019; Rauzana, 2016). Therefore, proactive conflict management concentrating on the approach to prevent or mitigate problems from the inception of the project is essential for effectively resolving conflicts and disputes (Mitkus & Mitkus, 2014). In another standpoint, rather than conflict management, it is more effective to address the problems in PPP to minimise subsequent disputes. By fostering awareness and offering targeted training on the causes and prevention of disputes, the construction project leaders can focus on improving the competencies of the procurement team.

3.4 PROFESSIONALS IN THE PROCUREMENT TEAM

"Procurement professional" is defined as an individual who possesses professional qualifications in procurement from a recognised institution and is expected to possess a range of skills to manage the procurement process (Basheka, 2010). Moreover, Kaufman et al. (2017) stated that procurement professionals are not 'purchasing agents', but managers who possess physical and intellectual knowledge.

Public Procurement and Asset Disposal Act No. 33 of 2015 defines a "Professional" as an individual possessing professional qualifications in a specialised area and who is engaged in practising a skill or trade and has completed relevant formal academic and professional training, including practical learning through apprenticeship or tutelage under the supervision of a suitably qualified and experienced individual in the relevant field. Jabar (2012) argued that pre-contract stage activities are carried out by a number of stakeholders, such as the employer and the design team professionals, such as Engineers, Architects, Quantity Surveyors, Land Surveyors, Landscape Architects and Interior Designers. Meanwhile, many researchers have highlighted that most of the problems occur due to errors caused by professionals such as Architects, Engineers and QSs, which leads to disputes (Yadollahi et al., 2014; Francis et al., 2022). Therefore, this research focuses on Engineers, Architects, and Quantity Surveyors from the above identified professionals who are involved in the procurement action in PPP. Similarly, under the Construction Industry Development (CIDA) Act no 33 of 2014, these qualified persons are identified as Engineers, Architects, and Quantity Surveyors who are in consultation with the relevant professional bodies in Sri Lanka. In order to have the best performance in procurement, it is crucial to have competent procurement professionals (Rathod, 2011 as quoted in Shehu et al., 2019; Chimwani et al., 2014).

3.5 COMPETENCIES REQUIRED FOR PROCUREMENT TEAM MEMBERS

Karna and Gotovac (2015) define competency as a combination of skills, knowledge, and abilities necessary to achieve satisfactory performance within an organisation. Moreover, Paloniemi (2006) defined competence as the integration of knowledge, skills and attitudes. Therefore, "Skill" is a subset of "Competency" which must be enhanced along with personal qualities (Karunasena et al., 2015). Knowledge refers to awareness of factual information, while skills refer to the ability to apply knowledge to specific circumstances (Baartman & de Bruijn, 2011).

Further, Briscoe et al. (2001) categorised skills as hard skills, which are primarily vocational, and soft skills, which are non-specific and acquired through on-the-job experience. According to Roggema-van (2004), a competent professional can apply the necessary expertise along with effective behaviour in practice. Furthermore, experience is a key competency that supplements educational qualifications and technical skills (Paloniemi, 2006).

Given the complexity of construction projects and the diverse nature of work involved in public procurement, procurement professionals are required to possess a wide range of skills, knowledge and experience to enhance procurement performance (Chimwani et al., 2014). Therefore, Fazekas and Blum (2021) emphasised the growing importance of identifying, developing and assessing the competencies of public procurement officers to ensure compliance with legislation and obtain VFM. Raymond (2008) stated that professionalism involves education, qualifications, and ethical conduct. Further, the

author contended that scholars have to showcase professionalism and competence while executing their responsibilities within their field of study. Jones (2007) argued that possessing procurement capacity involves understanding internationally recognised procurement principles, being knowledgeable about national laws, regulations and procedures, and maintaining a commitment to ethical responsibilities.

Summarised competencies and skills expected from Architects, Engineers and Quantity Surveyors are presented in Table 2 as identified by the reputed professional bodies and previous studies.

4. DISCUSSION

The study highlights the critical role of professional competencies, particularly among Architects, Engineers, and Quantity Surveyors in ensuring the success of public construction projects by effectively addressing issues prevalent in the PPP. Accordingly, the study identified 14 problems and 31 competencies. Out of the 14 problems corruption, and fraud risks, and poor-quality performance were the most frequently cited in the literature. While each profession has different roles, many important competencies are shared. For example, all three professionals need good communication, problem-solving, and decision-making skills. Findings further revealed that Engineers focus more on safety and planning, Quantity Surveyors handle cost and contracts, and Architects lead the design. However, by working together with the right mix of skills, problems and disputes in projects can be avoided. Even though soft skills such as teamwork, ability to act fairly and impartially are rarely highlighted, they are highly valued in professional standards, implying the importance in practice to avoid conflicts. Furthermore, the study emphasises the need for ethical conduct in public procurement to prevent corruption and ensure transparency.

Addressing competency gaps, by promoting the recruitment and training of competent procurement professionals for public procurement, not only improves individual project outcomes but also contributes to the broader objectives of sustainable development by promoting efficient use of public resources and delivering higher quality infrastructure that serves communities effectively.

. Table 2: Competencies expected from Engineers, Quantity Surveyors and Architects

Competency Group	Engineer		Quantity Surveyor		Architect

5. CONTRIBUTION OF THE RESEARCH

The findings of the research contribute to both academic fields and industry practice. For academia, the research provides a cornerstone for further studies to explore the linkage between identified problems and the competencies required to address them according to each profession. For the industry, it offers clients a better understanding of recruiting suitably competent professionals to their procurement teams while enabling professionals to self-direct competency development. Moreover, professional institutes can utilise the findings to conduct workshops, continuous professional development activities, seminars and courses to ensure that the respective professionals possess the lacking competencies. By promoting the recruitment and development of competency-equipped professionals, other than minimising disputes, this research also supports the integration of sustainability principles into procurement practices, contributing to the delivery of sustainable public construction projects.

6. CONCLUSIONS AND RECOMMENDATIONS

This study was designed to investigate the competency requirements of the professionals in the procurement team in the PCP by conducting a comprehensive literature review. PCP is often prone to problems such as time overrun, cost overrun and quality compromises, leading to disputes and challenging to this principle of "VFM". The study identified 14 problems, and it is essential to avoid these problems at first instance as they may consume a lot of money and time to resolve. It was understood that the problems could be overcome by building up the necessary competencies by the professionals in the procurement team. Architects, Engineers and Quantity Surveyors are mainly focused on the study since most of the problems stem from the activities performed by them. Accordingly, 31 relevant competencies were identified as essential for effectively addressing these procurement challenges and ensuring the success of public construction projects.

Based on the findings of the study, it is recommended that future researchers conduct empirical studies to establish links between the identified competencies and specific problems in the PPP. Moreover, a competency framework is recommended to develop linking each competency to the relevant professionals, which could serve as a practical tool for public sector recruiters to assess and select competent professionals for procurement teams, ultimately enhancing the effectiveness and accountability of PCP.

CONSTRUCTING NATIONAL POLICY FOR FUTURE GENERATIONS: A DESIGN APPROACH TO CHILDREN'S BOOKS

S. Samarawickrama[1]

ABSTRACT

Constructing policies that serve future generations requires approaches that are not only inclusive and forward-thinking but also grounded in the lived realities of their primary users, in this case, children. In 2023, the National Consortium for Children's Books (NCCB) was established in Sri Lanka to address challenges in the children's literature sector and fulfil national educational objectives. A central goal was the development of the National Policy for Children's Books (NPCB). This paper discusses the collaborative, design-driven approach utilized in formulating NPCB content, highlighting the innovative integration of design thinking into national policymaking. The process, structured through five iterative action research cycles, employed convergent and divergent thinking to identify systemic gaps, redefine stakeholder roles, and introduce specialized professional titles, such as 'Art Director', 'Creative Consultant', and 'Editor'. Ultimately, a unified publishing framework was crafted, specifically tailored to Sri Lanka's unique socio-cultural context, integrating fields like marketing, child psychology, design, and law to elevate the quality of children's books. One major outcome was the identification of essential policy content, articulated under eight goals that encapsulate the principles and values guiding the creation and distribution of children's books. This study illustrates the transformative potential of integrated design approaches within policymaking, providing a replicable model for similar global contexts. With the public review of NPCB launched in September 2024, this initiative represents a significant milestone in embedding design into the development of national policy frameworks towards a sustainable future.

Keywords: *Action Research; Children's Books; Design Thinking; Policy Development; Publishing Ecosystem*

1. INTRODUCTION

Developing national policies, performing research, and creating detailed guidelines are essential for enabling developing countries to address developmental challenges—such as poverty, inequality, and lack of access to education according to United Nations International Children's Emergency Fund and United Nations Children's Fund (United Nations Educational, Scientific and Cultural Organization, 2009; Wagner, 2014; World Bank, United Nations Educational, Scientific and Cultural Organization, & United Nations Children's Fund, 2021). However, sustainability often eludes these initiatives due to fragmented approaches within national book ecosystems (Altbach, 1993; Garzon, 2005; Jacobs, 1998; Hallewell, 1992). Countries like Sri Lanka face significant economic

[1]Senior Lecturer, Department of Integrated Design, University of Moratuwa, Sri Lanka, sumanthris@uom.lk

constraints that hinder the establishment and growth of robust publishing industries, which are further exacerbated by a limited market size, underdeveloped commercial infrastructure, and linguistic diversity (Garzon, 2005). Sri Lanka's challenges reflect broader trends in the Global South. For instance, South Africa experienced brief periods of publishing growth in the mid-20th century but did not achieve sustained success. Similarly, in Brazil, figures such as Juracy Feitosa Rocha attempted systemic change (Altbach, 1993), yet such initiatives often remained isolated. Economic instability, insufficient state planning, and inadequate cultural production channels consistently obstruct sustainable publishing industry development (Garzon, 2005).

Despite its adult literacy rate of 92.4%, Sri Lanka's local publishing industry faces compounded challenges, including inconsistent and fragmented policy efforts. As a developing country ranked 73rd on the Human Development Index, Sri Lanka also faces significant economic constraints (Knoema, 2024) that hinder sustainable book publishing efforts, despite its adult literacy rate having steadily increased from 2001 to 2021. Historical initiatives, such as the establishment of the 'Book Trust' in the 1960s under the Ministry of Cultural Affairs, failed to achieve their full potential and were eventually abolished by government authorities. Furthermore, UNESCO's global efforts between 1966 and 1972, through a series of regional meetings focused on book development, underscored the critical need for books—termed "book hunger", highlighting their importance for literacy and as essential tools for educational, scientific, technological, and socio-economic advancement. As a result, the meetings recommended the establishment of National Libraries among UNESCO member countries (Barker & Escarpit, 1973). Following these recommendations, the National Book Development Councils were established under the Ceylon National Library Services Board Act No. 17 of 1970 (Ceylon National Service Board Act, 1970). It was through this legislative framework that the National Library of Sri Lanka was later officially established on April 27, 1990. The Ceylon National Library Services Board was tasked with promoting library services and a reading culture across the country. Over time, this board evolved in function and structure. In 1970, it also facilitated the establishment of the Sri Lanka National Book Development Board, which focused specifically on promoting the publishing industry and book development. Later, through Act No. 51 of 1998 (National Library and Documentation Services Board Act, 1998), the original Ceylon National Library Services Board was restructured and renamed the National Library and Documentation Services Board (NLDSB). The National Library and Documentation Services Board (NLDSB), operating under the Ministry of Education, is responsible for developing and coordinating library services, documentation, and information management across Sri Lanka. Since 1984, the NLDSB has managed the Publication Assistance Project, aiming to support authors and enhance the quality of local publications (National Library of Sri Lanka, n.d.). Meanwhile, the Sri Lanka National Book Development Board was re-established in 2018, aiming to revive and consolidate efforts to support national book development, publishing standards, and stakeholder coordination. However, in 2022, the Sri Lankan government formally dissolved the National Book Development Council, citing concerns over its performance and aligning the decision with a broader national agenda to streamline and restructure state institutions, following a cabinet directive (Ministry of Education, 2022). This move reflected persistent political challenges in maintaining a cohesive and sustainable national book development policy framework.

Despite these structural shifts, Sri Lanka has witnessed consistent yet isolated progress in publishing-related efforts. Notable contributions have come from the National Library of Sri Lanka, which has published several guidelines and handbooks. Among these include the handbook titled *"Methodology of Children's Book Composition: A Pilot's Guide to the Layout of the Front Pages, Table of Contents, and Back Pages of a Children's Book"* (Gunathilake & Bopitiya, 2018). Another key initiative was a national research project conducted in collaboration with the School Library Development Branch of the Ministry of Education, titled *"Evaluation of Children's Literature"* (Ministry of Education, 2019). These efforts highlight the relevance of individual stakeholder contributions, although they often function in silos without coordinated alignment.

Similarly, Room to Read – Sri Lanka, an international non-governmental organization (INGO) working in partnership with the Ministry of Education, has made significant contributions to children's literacy through its extensive programmes. These include the publication of high-quality children's books and capacity-building workshops for local writers and illustrators (Room to Read, 2014). However, due to INGO regulations, these books are not commercially sold, resulting in limited distribution and access. In higher education, institutions such as the National Institute of Library and Information Sciences (NILIS) at the University of Colombo, and the Department of Library and Information Science at the University of Kelaniya, continue to offer Library Science education that emphasizes the importance of reading, literature, and information management (University of Colombo, n.d.; University of Kelaniya, n.d.). Additionally, the University of Moratuwa offers a studio-based project on book and editorial design as part of its Bachelor of Design Degree Programme at the Department of Integrated Design, within the Media and Communication Design specialization stream (University of Moratuwa, n.d.). While undergraduates frequently develop book concepts and design prototypes, the transition to publication remains limited due to insufficient collaboration with the commercial publishing sector.

Meanwhile, the Sri Lanka Book Publishers Association plays a critical role in sustaining the industry through book production and imports. It also organizes major public events, including Sri Lanka's largest book fairs in Colombo and Kandy, helping to promote reading and generate economic benefits for all member publishers (Sri Lanka Book Publishers Association, n.d.).

Despite these diverse and meaningful initiatives, the lack of integrated collaboration among key stakeholders of the private and public sectors responsible for creation, publishing, distribution, knowledge dissemination, and review continues to hinder the growth of a cohesive national publishing ecosystem. Most critically, these efforts often overlook the most important stakeholder: the child reader, whose needs and perspectives should be at the heart of every publishing initiative. Therefore, the aim of this research is to develop the content and structure of Sri Lanka's National Policy for Children's Books (NPCB) through a design-led, action research methodology, in order to address systemic fragmentation in the children's publishing ecosystem and create a sustainable, inclusive, and child-centred policy framework.

2. BACKGROUND: NCCB AND THE DESIGN-DRIVEN POLICY APPROACH

In response to the recognized lack of collaboration within the Sri Lankan publishing industry, the National Consortium for Children's Books (NCCB) was established in 2023 with discussion that began in 2022 with the above-mentioned and many other members representing the children's book publishing ecosystem of Sri Lanka (Ministry of Education, 2022; National Consortium for Children's Books [NCCB], 2023). The NCCB is spearheaded by the Educational Publication Advisory Board of the Ministry of Education with Room to Read (RtR), Sri Lanka, which supports children's literature through extensive global experience. Leveraging their expertise and funding support, the NCCB incorporates key stakeholders from various institutions including the National Institute of Education (NIE), the National Library and Documentation Services Board (NLDSB), the Primary Education Branch of the Ministry of Education, and members representing state universities involved in relation to the book publishing ecosystem-University of Colombo, University of Kelaniya University and University of Moratuwa.

The NCCB was established with the aim of enhancing the quality and global competitiveness of Sri Lanka's children's literature by addressing long-standing fragmentation in the sector. A central outcome of this collaborative effort was the formulation of the National Policy for Children's Books (NPCB), which focused on its most essential stakeholder: the child reader.

To formulate the required content for the National Policy for Children's Books (NPCB), it was essential to identify root causes and systemic gaps within the publishing ecosystem, while prioritizing the needs of child readers. To achieve this, the appointed Editor-in-Chief of the NPCB—who is also the author of this paper—collaborated in a series of workshops using both divergent and convergent thinking techniques. These workshops involved discussions, focus group activities, mapping exercises, and iterative content drafting. Initiated in July 2023, these activities are still ongoing. However, this paper focuses specifically on the process leading up to the public review of the NPCB, launched in September 2024 (National Consortium for Children's Books, 2024; Presidential Media Division, 2024; Onlanka News, 2024). Drawing on her background as a design educator and member of the NCCB, the Editor-in-Chief approaches the identification and development of policy content as a 'design problem.' Design is fundamentally understood as a problem-solving activity, encompassing cognitive processes such as creativity, iteration, and analogy (Meslec, Graff, & Clark, 2020; Wiltschnig, Christensen, & Ball, 2013). Accordingly, this paper frames the development of NPCB content as a response to an authentic human need, shaped through innovative, interdisciplinary, and adaptive design approaches. As Victor Papanek asserted in Design for the Real World, design must serve as a highly creative, cross-disciplinary tool capable of addressing genuine human needs effectively (Amir, 2004).

3. METHODOLOGY: A DESIGN THINKING FRAMEWORK

Design emerges as a critical tool for bridging theory and practice (Holmström, Ketokivi, & Hameri, 2009; Nijhawan, 2017). Often described as both a verb and a noun, design encompasses the processes of planning, creating, and adapting means to achieve specific ends (Buchanan, 2001). This dual nature underscores design's problem-solving, creative,

and cognitive dimensions, making it an ideal approach for addressing systemic challenges in policy-making (Amir, 2004; Cross, 2001). In this study, the aim was to identify and develop policy content framed as a 'design problem' within the fragmented children's book publishing ecosystem, placing the child as the key stakeholder and end-user.

To solve the defined 'design problem'—which also served as the core research question—a series of three residential programmes and a pilot training initiative in children's book creation (focused on picture books) were conducted from July 2023 to August 2024. These initiatives began with a series of workshops aimed at identifying and defining the problem, followed by the development and delivery of practical solutions. The overall design application was implemented through five iterative action research cycles. Each cycle served a distinct purpose: (1) Identify and Review, (2) Formulate and Clarify, (3) Define, (4) Map, and (5) Establish (see Figure 1 for an overview of the five cycles of action research). These phases align with the foundational structure of action research—identifying a problem, planning, taking action, observing outcomes, and reflecting for improvement (Kemmis & McTaggart, 1988; Reason & Bradbury, 2008). However, this research reframed those steps through a design thinking lens, aligning each cycle with the needs of the children's publishing ecosystem and the developmental focus of the policy.

4. THE ITERATIVE PROCESS OF THE FIVE ACTION RESEARCH CYCLES

The five action research cycles were conducted as iterative, participatory inquiries, each structured around the core phases of planning, acting, observing, and reflecting. This cyclical framework allowed the research to remain responsive and grounded in stakeholder input.

4.1 CYCLE 01

Focused on identifying and reviewing existing content relevant to the development of the NPCB. This involved a literature review conducted by two working groups: Group 1 focused on the author, editor, and content development perspective, while Group 2 examined illustration and design aspects of children's books.

The outcome of this stage resulted in two distinct presentations. Group 1 systematically structured the content and outlined key aspects for inclusion in the policy, such as the definition of a child, book types and genres, social and cultural context, forms of editing, knowledge of literature, specifics related to Sri Lanka (including the Sinhala and Tamil communities), language use, and more. Meanwhile, Group 2 highlighted gaps in the literature on aspects like remuneration, illustration styles, the need for specialized editors focusing on visual and narrative elements, the necessity of a standardized or fair payment plan, agreements between publishers and authors, inclusivity of gender and culture, involvement of various stakeholders, and the requirements of children as the end users of the books (Education Publication Advisory Board & Ministry of Education, 2023).

Overall, this stage identified a wide range of content to be included in the policy and recognized the undocumented nature of stakeholder roles and publishing practices in Sri Lanka's children's book ecosystem. This insightful discovery necessitated the next approach.

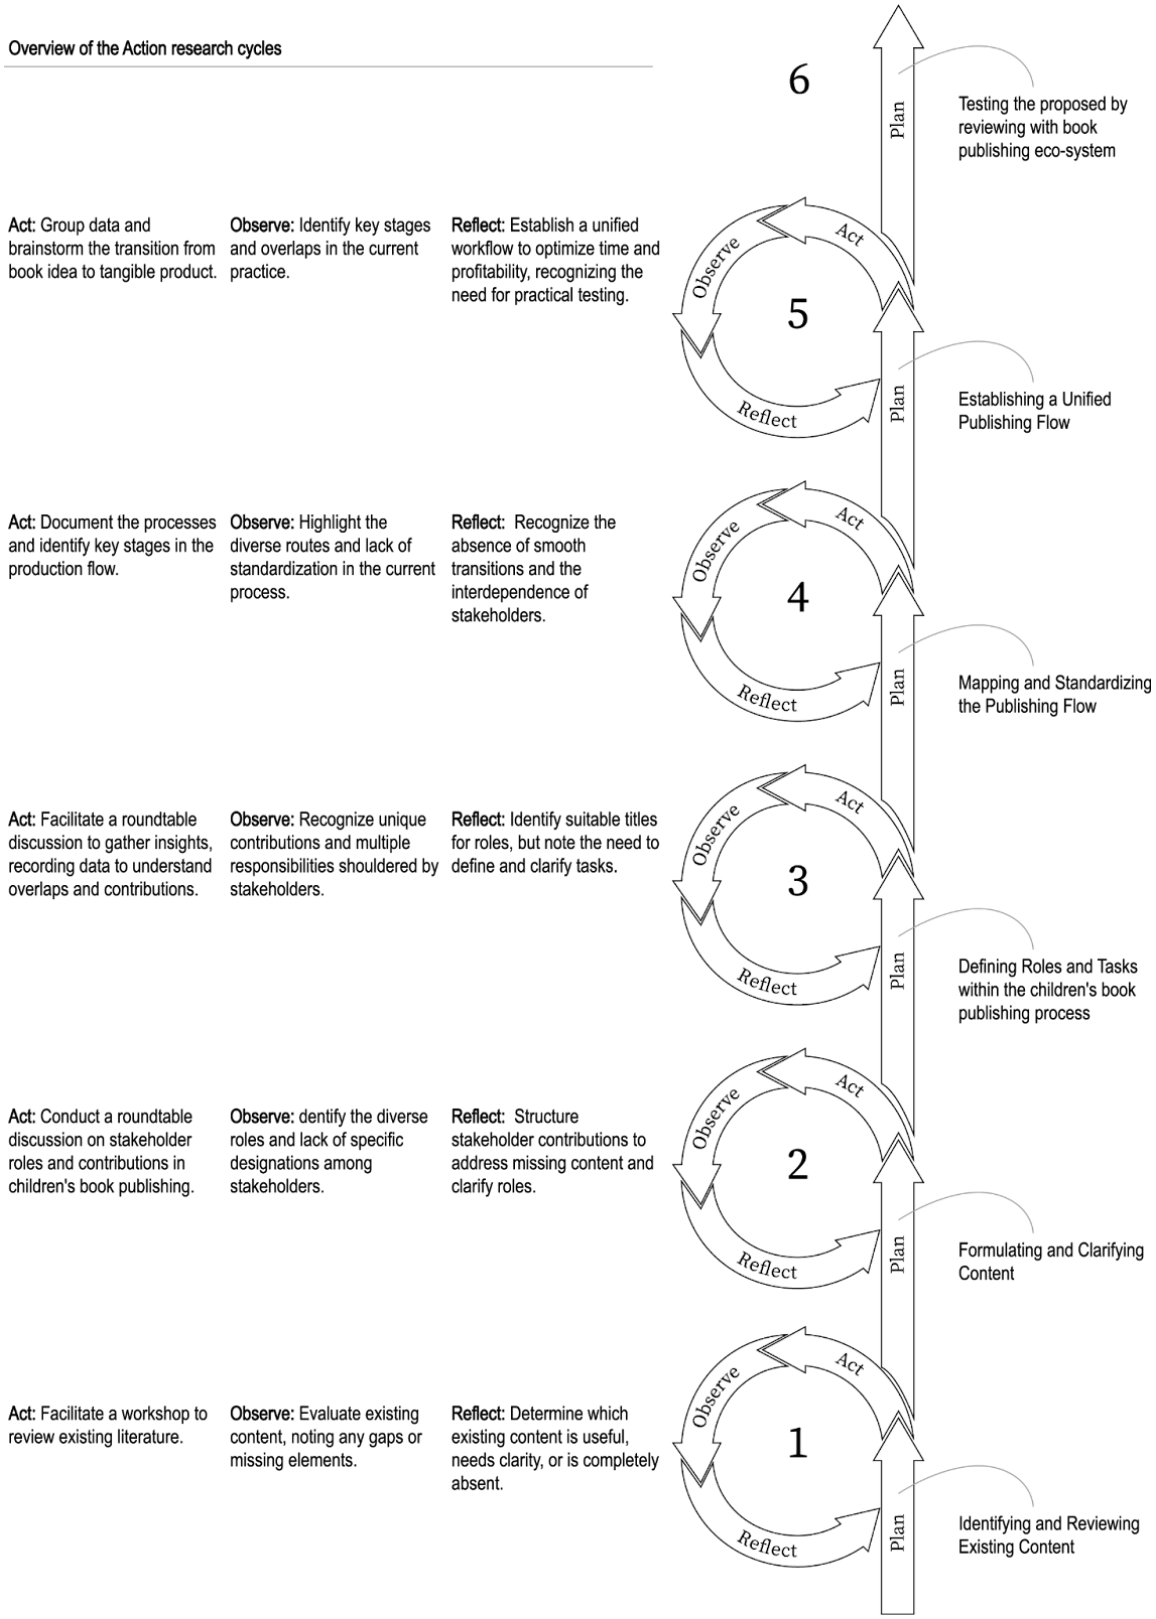

Figure 1. Overview of the five action research cycles

4.2 CYCLE 2

Focused on clarifying missing data and structuring the previously undocumented elements. It sought to define the roles and contributions of stakeholders within current publishing practices. This cycle was conducted through a roundtable discussion, where participants articulated their tasks, responsibilities, and professional designations within the publishing process. The session featured a diverse range of contributors, including writers, illustrators, language editors, translators, educators, policymakers, publishers, readers, and critics, who shared valuable insights from both local and international experiences.

Participants compared their roles and reflected on overlapping functions in the book production process. A key finding during this stage was the absence of formal education or training programmes in children's publishing in Sri Lanka. The discussions revealed that most professionals in the sector are self-taught, leading to varying skill levels and informal role definitions. For instance, after an illustrator completes their work, files are passed to individuals with titles such as typesetter, layout artist, digital designer, or simply designer, despite differing technical responsibilities. These individuals may be part of a publishing house, a print bureau, or freelance networks (Education Publication Advisory Board & Ministry of Education, 2023).

This stage confirmed the existence of pivotal yet inconsistently named roles in the children's book publishing process. It highlighted the urgent need for formal recognition of professional designations and clearer task descriptions aligned with global standards.

4.3 CYCLE 3

Focused on defining roles and tasks within the children's book publishing process. This stage included a round-table discussion to gather insights and document data, with the aim of clarifying designations and determining appropriate titles for individuals contributing to the publishing journey. Key questions addressed during the session included: What is each participant's role? What professional title do they hold? What is the equivalent international title? What specific tasks do they undertake, especially when fulfilling multiple roles?

The findings revealed that most stakeholders perform several duties across different stages of the publishing process. For example, a publisher might play a central role in the book launch phase but have limited involvement during the creation stage. Similarly, an illustrator proficient in design software may also function as a typesetter during both the creation and production phases. Furthermore, roles such as 'language editor' and 'translator' frequently overlap with other responsibilities due to the lack of formally trained professionals and the prevalence of self-taught individuals in the industry. This multitasking often results in higher compensation for individuals and reduced labour costs for publishers (Education Publication Advisory Board & Ministry of Education, 2023).

As part of this cycle, efforts were made to align locally used titles with international standards. For instance, the role commonly referred to as 'designer' in the Sri Lankan context was mapped to international designations such as 'art director,' 'book editor,' 'book designer,' or 'editorial designer'. Conversely, individuals primarily focused on layout and print production were more accurately described as 'typesetters,' although the broader label 'designer' remains widely used. The discussions highlighted the flexible and sometimes ambiguous use of these titles, emphasizing the need to formalize and

distinguish professional designations, especially in the absence of a regulatory framework in the Sri Lankan publishing sector.

The discussion led to the classification of existing roles and the recommendation to introduce new titles while phasing out those that no longer align with international best practices. For instance, the title 'designer' was proposed to be redefined as 'art director'—a new designation in the Sri Lankan context—while the current use of 'designer' was recommended to be replaced with 'typesetter' to avoid misinterpretation. The finalized list of titles was considered representative of the key stakeholder roles in the Sri Lankan publishing industry. In cases where responsibilities remained unclear, the stakeholder's title was noted for further review.

This cycle identified approximately 15 stakeholder titles and underscored the need to formalize and expand professional designations to address current gaps in practice. It emphasized the importance of clearly articulating each stakeholder's roles and responsibilities within the publishing journey, laying the groundwork for the next stage of the research (Education Publication Advisory Board & Ministry of Education, 2023).

4.4 CYCLE 4

Focused on mapping the actual publishing routes followed by the stakeholders identified in the previous cycle. A large whiteboard served as the primary visual tool, featuring a sketch of a human stick figure on the far left to represent stakeholders, and a series of illustrated children's books on the far right to symbolize the diversity of existing and potential genres and formats. Participants were asked to envision themselves as the stick figure and narrate their journey toward creating a published children's book.

Data were gathered through both individual reflection and collaborative discussion. Participants described their journey from ideation to final product, highlighting key stages where multiple stakeholders collaborate to achieve shared outcomes. For instance, during the printing phase, although each stakeholder is responsible for a different task, their collective objective remains the same: to deliver a complete, high-quality book.

Through this collaborative mapping process, 16 key stages in the existing publishing workflow were identified. However, it became evident that many of these stages involved overlapping responsibilities (Education Publication Advisory Board & Ministry of Education, 2023). For example, after the initial stages of ideation, plot development, and story sketching, some authors approached publishers directly, while others collaborated with illustrators first. These variations revealed inconsistencies, inefficiencies, and redundancies within the current system.

As a result, this cycle highlighted the urgent need to reduce overlaps and streamline the publishing process by clearly identifying, naming, and sequencing the key stages of children's book production in Sri Lanka.

4.5 CYCLE 5

Focused on establishing a unified, linear workflow that all stakeholders could adopt—thereby optimizing time, improving collaboration, and enhancing profitability. The previous cycle had confirmed that stakeholders within Sri Lanka's children's publishing industry follow different, often fragmented, routes to produce a published book. To address this, the workshop coordinator—who is also the author of this paper—introduced

the concept of transitioning from an intangible product (a book idea) to a tangible, market-ready publication.

All previously mapped and divergent publishing paths were consolidated into a coherent linear process with the active participation of workshop attendees at the third residential programme. A brainstorming session was conducted, during which the five stages of the Stanford Design Thinking method were restructured and expanded into eight clearly defined stages. Each stage was paired with a guiding question to ensure clarity of purpose and to align stakeholder responsibilities. Particular attention was paid to clarifying roles for individuals handling multiple responsibilities (Education Publication Advisory Board & Ministry of Education, 2023).

For example, if an individual functioned as both publisher and printer, this framework enabled them to differentiate their tasks within each stage. In cases where roles such as 'art editor' were previously undefined in the Sri Lankan context, this process also outlined necessary responsibilities and highlighted opportunities for training and professional development.

The outcome of this cycle was the formulation of an eight-stage linear publishing model, ranging from ideation to impact. (1) The Ideation Stage focused on identifying the initial inspiration and exploring the intangible concept of a children's book (What sparked the creation of this book, and how will it fulfil the needs of its audience?). (2) The Refining Stage emphasized evaluating and refining the idea based on child-focused and market considerations (How will the book be developed to align with children's needs and preferences?). (3) Empathizing with Stakeholders involves clarifying the roles and contributions of all participants in the publishing process (Who will be involved, and what additional expertise is required?). (4) The Prototyping and Production Readiness stage centred on finalizing content, illustrations, and administrative requirements (What steps are needed to make the book production-ready?). (5) Empathizing and Testing ensured the book met audience and stakeholder expectations through final feedback loops (What adjustments are necessary before printing?). (6) The Finishing Stage addressed final production checks and market preparation (Are all aspects finalized and have stakeholder concerns been addressed?). (7) Launching and Promotional Efforts planned the introduction of the book to its audience (How will the book reach children, and what promotional strategies are planned?). Finally, (8) Scaling and Impact ensured the book's broader reach. They assessed its effect on children's reading experiences (What impact does the book have, and how is it sustained within educational ecosystems?) (National Consortium for Children's Books, 2024; Presidential Media Division, 2024; Onlanka News, 2024).

The structure of this research aligns with the Double Diamond framework, which outlines a design process through phases of divergent and convergent thinking. The first diamond—composed of Cycles 1 and 2—focused on discovering and defining the policy problem through participatory exploration and clarification of stakeholder perspectives. The second diamond—encompassing Cycles 3 to 5—emphasized the development and delivery of a coherent policy solution, culminating in a unified publishing framework. The visual model below (Figure 2) illustrates how these five action research cycles map onto the Double Diamond process, demonstrating the transformation of fragmented publishing practices into a structured national policy framework.

This stage concluded with the confirmation of a finalized linear production flow, offering a replicable model for the Sri Lankan publishing industry. It also marked the transition to a critical next step: identifying and articulating the scope of the policy across four key areas— (1) Producing Quality Books Over Quantity, (2) Understanding the Child Reader's Psychology and Development, (3) Standardizing the Publishing Process, and (4) Defining Roles and Responsibilities of Stakeholders. These thematic areas were then expanded into eight clearly defined goals, which collectively serve as the foundation for formulating the mission and vision of the National Policy for Children's Books (NPCB).

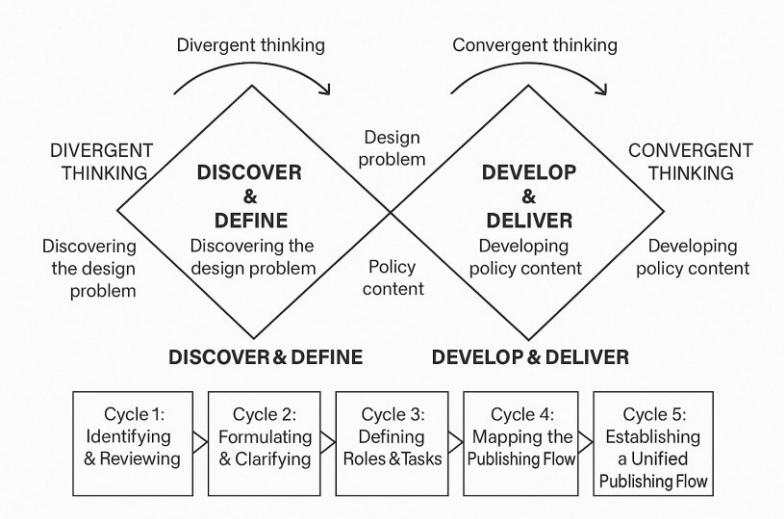

Figure 2. Mapping the five action research cycles to the double diamond framework

5. DISCUSSION

The formulation of the NPCB content was grounded in a design-led methodology, which unfolded through five iterative action research cycles. Each cycle served as both an exploratory mechanism and a diagnostic tool to respond to the fragmented publishing ecosystem, but also as a diagnostic tool, highlighting challenges that demanded policy-level interventions.

Table 1 summarizes the five action research cycles and how each contributed to the scope, goals, and vision of the National Policy for Children's Books (NPCB). Rather than emerging from abstract or predetermined frameworks, the policy goals were developed organically from the issues identified within each action cycle. This ensured that the goals addressed practical publishing gaps and stakeholder needs, while remaining anchored in the developmental requirements of the child, the primary user.

Cycle 1, Identifying and Reviewing Content, revealed a lack of cohesive content frameworks and underscored the scarcity of child-focused, culturally relevant, and developmentally appropriate materials. For instance, while some existing books promoted literacy, they lacked systematic attention to genre, age appropriateness, and Sri Lankan socio-cultural identity. These insights directly contributed to the articulation of the goals: Enhancing Quality and Accessibility and Supporting Child Development. The need to shift from quantity to quality, and to ground publishing decisions in developmental psychology (e.g., Piaget's stages), also emerged from this cycle.

Cycle 2, Formulating and Clarifying Stakeholder Roles, uncovered blurred and overlapping professional responsibilities. This ambiguity highlighted the need for a goal focused on building a Collaborative Ecosystem and another aimed at Promoting Inclusivity and Equity. The process of clearly defining roles, while advocating for the equitable inclusion of both formally trained and self-taught professionals, responded directly to these structural gaps.

Table 1: Summary of action research cycles and their contribution to policy scope, goals, and vision

Cycle	Purpose	Contributed to Policy Scope	Related Policy Goals	Link to NPCB Vision
Cycle 1: **Identify and Review**	Identified gaps in child-focused content, literature standards, and Sri Lankan socio-cultural representation.	Understanding the Child Reader's Psychology and Development	Enhancing Quality and Accessibility; Supporting Child Development	Rooting content in child development needs
Cycle 2: **Formulate and Clarify**	Clarified stakeholder roles and contributions; addressed informal and overlapping responsibilities.	Defining Roles and Responsibilities of Stakeholders	Building a Collaborative Ecosystem; Promoting Inclusivity and Equity	Equitably involving all contributors
Cycle 3: **Define**	Classified professional titles and aligned local roles with international standards.	Aligning Roles and Standards with Global Practices	Aligning with Global Standards; Positioning Sri Lanka as a Global Contributor	Elevating professional standards for global relevance
Cycle 4: **Map**	Mapped fragmented publishing flows and identified inconsistencies across stakeholder pathways.	Standardizing the Publishing Process	Sustainable Publishing Practices; Encouraging Lifelong Reading	Creating streamlined, repeatable production workflows
Cycle 5: **Establish**	Developed and finalized a unified eight-stage publishing model with guiding questions and standardized processes.	Producing Quality Books Over Quantity	All eight goals synthesized and finalized	Translating findings into a visionary, actionable policy framework

Cycle 3, Defining Roles and Tasks marked a turning point in role classification. Through guided questions such as "What is your professional title?" and "Which international title aligns with your role?"—participants revealed the absence of recognized professional

standards. For example, individuals referred to as "designers" were often functioning solely as typesetters or layout artists, which diverged from global norms. These revelations informed the goals of Aligning with Global Standards and Positioning Sri Lanka as a Global Contributor. This cycle underscored the value of international benchmarking to elevate the global standing of Sri Lankan literature.

Cycle 4, Mapping the Publishing Flow, exposed redundancies, bypassed stages, and inconsistent workflows. For example, some authors skipped editorial reviews entirely or proceeded directly to print with unstructured manuscripts. These inefficiencies indicated a lack of standardized publishing procedures. As a result, the policy introduced goals related to Sustainable Publishing Practices and Encouraging Lifelong Reading. By formalizing the publishing process, the policy aimed not only to ensure quality but also to support a child's continuous engagement with books from ideation to access.

Cycle 5, Establishing a Unified Publishing Flow and Finalizing Policy Content synthesized the findings of all previous cycles and culminated in the development of an eight-stage linear production model—from ideation to impact. Each stage incorporated a guiding question to provide stakeholders with a clear purpose aligned with policy objectives. This model served as the operational backbone of the NPCB, supporting all eight policy goals, including sustainable systems, equitable distribution, and global competitiveness. Importantly, the conclusion of this cycle initiated the formal articulation of the NPCB's vision, mission, and strategic goals.

6. CONCLUSION

The five cycles were more than research phases, they were diagnostic, iterative, and participatory processes that applied the core tenets of design thinking. Divergent thinking facilitated the identification of multiple perspectives and overlooked problems; convergent thinking enabled the structuring of these insights into actionable solutions.

By reframing systemic publishing challenges as "design problems," the policy development process became deeply grounded in real needs rather than assumptions. Each cycle acted as a mirror, reflecting the industry's current state, and as a compass, directing the course of reform. The outcome the NPCB's vision and eight strategic goals—is a direct response to these findings, grounded in reality.

This approach demonstrates how design thinking, when embedded into national policy-making, can lead to practical, inclusive, and adaptive frameworks. It offers a replicable model not only for other cultural sectors in Sri Lanka but also for global contexts where design, education, and policy intersect.

With the public review of the National Policy for Children's Books launched in September 2024 (National Consortium for Children's Books, 2024; Presidential Media Division, 2024; Onlanka News, 2024), this initiative marks a significant milestone in embedding design into the development of national policy frameworks. It reflects a forward-thinking commitment to creating a sustainable, collaborative, and child-centered publishing ecosystem—one that serves both current educational needs and the aspirations of future generations.

As this iterative process continues to unfold, the feedback gathered through public consultations and focused group discussions with relevant authorities will further refine and strengthen the policy. Thereafter, the NPCB is on course to be presented for Cabinet

approval, positioning it as a model for policy development through inclusive, design-led innovation.

7. ACKNOWLDGEMENTS

The author extends sincere gratitude to the National Consortium for Children's Books (NCCB) and the Ministry of Education, Sri Lanka, for their leadership. Appreciation is also expressed to Room to Read – Sri Lanka, the Sri Lanka Book Publishers Association, and the Department of Integrated Design at the University of Moratuwa for support throughout the process.

Special acknowledgment is given to participants who contributed to workshops shaping this policy. The author further thanks the Ministry of Education for hosting the draft policy for public review in September 2024 to encourage broader input.

COPING STRATEGIES ADOPTED BY INHABITANTS WITH ASBESTOS CEMENT ROOF HOUSES IN SOUTH AFRICAN LEGACY TOWNSHIP

Nonhlanhla Maphoso[1] and Christopher Amoah[2]

ABSTRACT

The apartheid regime's housing development policy, whereby asbestos was used in roofing these houses, still exists in several towns in South Africa. One such community is Phomolong, where several houses are still roofed with dilapidated asbestos, posing a threat to households living in these houses. The study aimed to ascertain the coping strategies adopted by the inhabitants to navigate the challenges posed by the asbestos-cement roofing in Phomolong. A qualitative research approach was adopted to interview inhabitants living in asbestos-cement-roofed houses in Phomolong via face-to-face interviews with a structured interview guide. The interviews were recorded, transcribed and analysed using a thematic content analysis approach to identify main and sub-themes. The findings show that Phomolong inhabitants with asbestos-cement roofed houses experience several challenges. In coping with these challenges, inhabitants adopt strategies including placing materials such as tyres and rocks on roofs, sealing and painting roofs inside, placing buckets when it rains, and using binding wire on walls to hold roofing, among others. Due to the post-apartheid government's slow pace in replacing asbestos-cement roofing from legacy houses, inhabitants continue to experience hardships, forcing them to adopt an unconventional strategy to survive living in these houses. This situation, therefore, leaves them exposed to dangers associated with asbestos, posing further health risks to the community. The study contributes to the growing academic knowledge of challenges related to asbestos-containing material (ACMs) in non-occupational settings. It has outlined the lived experiences of a legacy township's inhabitants in South Africa, challenges and strategies they used to contain them, thereby making their plight further known to the government for possible intervention.

Keywords: *Asbestos; Cement Roof; Coping Strategies; Houses; Legacy Townships; South Africa.*

1. INTRODUCTION

South Africa's asbestos cement roofs have come into the spotlight with media coverage of the State Capture Commission's report. As a result, there has been public fear regarding the possible impacts of asbestos cement roofs in non-occupational settings (Gibson et al.,

[1] Department of Quantity Surveying and Construction Management, University of the Free State, South Africa, 2018122446@ufs4life.ac.za
[2] Department of Quantity Surveying and Construction Management, University of the Free State, South Africa, amoahc@ufs.ac.za

2021). Communities will continue to live with these asbestos cement roofs for decades before removing them completely, making it essential for academia to bring attention to the challenges associated with them (Gibson et al., 2021). This study investigates the challenges that inhabitants face in asbestos-cement roofed houses in a South African legacy township of Phomolong. Some previous studies believe there is no scientific proof outlining the exposure threshold free from asbestos; as such, all forms of asbestos are carcinogenic (Frank & Joshi, 2014). Additionally, Kottek and Yuen (2021, p.158) state that "the measurability or non-measurability of risk does not indicate the public health significance of the risk". This means that epidemiology has limited ability regarding the measurability of people living or working around Asbestos-Containing Materials (ACMs); such communities living with these materials cannot be ruled out of risk.

The traditional perspective that does not see ACMs as a risk argues that asbestos bound to some bonding agent, such as cement, posed no danger. However, there is growing evidence that this is not the case, as these ACMs age and can get damaged (Ervik et al., 2021). ACMs can be regarded as materials that create an ongoing risk of asbestos exposure. This could result from renovations, damage, replacement, weathering or natural disasters (Kottek & Yuen, 2021). In support of this statement, Oberta et al. (2018) illustrated that uncoated asbestos fibres get released. Similarly, Ervik et al. (2021) found that asbestos cement roof weathering in the layer of loosely bound fibres on the surface occurs.

According to the National Institute for Communicable Diseases of South Africa (NICD) (2010), reporting on a study conducted by Phillips et al. (2009) states that the presence of asbestos cement roofs on houses that were built over 50 years ago presented a concern. This provides more evidence than what had initially been erroneously found in previous studies. Phillips et al. (2009), using 61 households, provided evidence that asbestos was present in the soil around all these houses. It was proven that weathering of asbestos cement roofs around these houses had occurred and resulted in the leaching of asbestos.

Considering the findings by Phillips et al. (2009), it can be suggested that all asbestos exposure should be regarded as a risk. Thus, the presence of asbestos cement roofs in Phomolong poses risks for the residents. According to Bates (2020), asbestos abatement continues to be slow in the Free State province; thus, the effects of these asbestos cement roofs on the residents should indicate the sense of urgency for their removal, especially those damaged. Additionally, some households scheduled for the asbestos removal project in the Free State are uninformed of the dangers of damaged asbestos cement roofs (Felix, 2021). Despite these ascertions, past studies have not significantly dealt with how inhabitants staying in these houses manage to navigate the challenges posed by these dilapidated asbestos-roofed houses. For instance, Bates (2020) focused on the corrupt activities associated with the asbestos roof removal in the Free State, whilst Cilia et al. (2025) focused on the weathering aspects of the asbestos roof. Likewise, Gibson et al. (2021) and Kottek and Yuen (2021) focused on the health aspects of asbestos cement roofs on inhabitants. As such, it is necessary to identify how the residents of Phomolong are coping with the challenges posed by the dilapidated asbestos roofing and make it known to the policy implementers.

2. LITERATURE REVIEW

2.1 ASBESTOS CONCEPT

According to Hart (1988), the term asbestos has a Greek origin and stands for an "inextinguishable flame". Asbestos refers to a group of fibrous silicate minerals (Cilia, et al., 2025). These naturally occurring minerals are broadly grouped into two types, namely, amphiboles and serpentines. When assessed microscopically, one key differentiating characteristic is that straight needle-shaped fibres characterise the amphibious group, while the serpentine group has spiral fibres (Frank & Joshi, 2014; Hart, 1988).

The amphiboles group consists of amosite, crocidolite, tremolite, anthophyllite, and actinolite, respectively, commonly referred to as brown-, blue-, grey-, yellow-, and green-asbestos. In contrast, serpentines mainly consist of only one type of asbestos, named chrysotile, commonly known as white. Only the amosite, chrysotile and crocidolite were mined in South Africa (Hart, 1988). Globally and in South Africa, the commonly found asbestos type used in producing ACMs (such as asbestos cement roofs) is chrysotile (Frank & Joshi, 2014). The popularity of using ACMs in construction was attributed to the asbestos mineral characteristics: impeccable heat resistance, durability and somewhat weatherproof (Ervik et al., 2021). Additionally, the low-cost factor that these products offered made them a common choice. There are over 3000 products in which asbestos has been used (Subramanian & Madhavan, 2005). These products were used in construction and industries such as power engineering, transport, and textiles (Szymanska & Lewandowska, 2019).

2.2 ACM MANAGEMENT AND REMOVAL CHALLENGES

Studies documenting asbestos cement roof weathering specifically can be traced back to the 1980s (Spurny, 1989). According to a Polish study by Szymanska and Lewandowska (2019), several challenges can arise during the disposal of asbestos or ACMs. The first is that the co-financing mechanisms to facilitate removal projects can have slow implementation. Secondly, they do not have a complete inventory list of existing ACMs and locations. This can result in incomplete information for proper management and removal project planning. The third is that in cases where government interventions are not in place, not all communities have prepared or have the means to organise their ACM removal projects. As such, they continue living with them (even when damaged). The last challenge is that society may have a high number of people with little awareness of the harmful effects of asbestos waste on human health or how to properly handle the removal of such material to minimise atmospheric dispersion of the asbestos fibres.

In Africa, where several countries are dealing with ACMs installed over fifty years ago, are now presenting a problem of hazardous waste management and have been associated with other varied problems (Gebremedhin et al., 2018). According to Lacourt et al. (2013), irrespective of the considerable academic interest in studies related to exposure to asbestos, be it directly or indirectly or the aftereffects, there is still a vast number of countries that produce or use ACMs and those that use poor ACM disposal methods.

2.3 LEGISLATION RELATED TO ACMS IN SOUTH AFRICA

Nationally, the phasing out of asbestos in South Africa began in 2004 and was solidified by the approval of regulations prohibiting the use, processing, and import/export of asbestos or ACMs in 2008 under the guidance of the Environment Conservation Act of 1989. Initially, it regulated asbestos and ACMs through the Asbestos Regulation (2001), which related to the employer or self-employed person. This restricted them from doing work that may harm any person because of asbestos exposure. However, this regulation was repealed by the Asbestos Abatement Regulations (2020), which came into effect on 10th November 2020, with exceptions on two regulations (regulations 3 and 20) only coming into effect 18 months after the effective date mentioned. This change has made regulations more aligned with international standards, such as the clear labelling of asbestos waste as per United Nations (UN) Recommendations on transporting dangerous goods (Collier & Ilsley, 2020).

As per the regulations, several conditions must be met when conducting ACM removal activity. These are:

1. A registered asbestos contractor must carry out the work (types 2 and 3) with an asbestos removal certificate.
2. Before the removal, all asbestos materials that may become airborne must be identified to prevent exposure and adequate control measures must be placed.
3. The handling and disposal of the ACM must be done following Regulation 21 of the Asbestos Regulations 2020.
4. When the removal and disposal of existing asbestos roof sheets are completed, a certificate that indicates the safe disposal of the hazardous material must be produced.

Some of the differences between the old and new regulations include dividing work into three types of asbestos. Under the new regulations, only types two and three require that they be carried out by contractors registered as asbestos specialists. Additionally, now it is mandatory to conduct an asbestos inventory and risk assessment and to create a management plan for removal, repairs and phasing out (Collier & Ilsley, 2020).

3. RESEARCH METHODOLOGY

3.1 RESEARCH APPROACH

This research adopted the qualitative research approach. The quantitative research approach is regarded as objective in nature, while qualitative research is subjective. Creswell & Creswell (2017) define qualitative research as an approach that explores the understanding and meaning of a social or human problem experienced by an individual or a group. The decision on which approach to adopt mainly depends on the purpose of the study and the type of data required (Naoum, 2019). Since the study's purpose is to ascertain the lived experiences of how inhabitants with dilapidated asbestos-cement roofed houses cope, the qualitative research approach was suitable as it allowed the researcher to focus on gaining in-depth stories of the participants.

3.2 TARGET POPULATION AND SAMPLING METHODS

The population of this study consisted of the inhabitants of asbestos-cement roofed houses in the Phomolong township. The study adopted the purposive sampling method.

Purposive sampling was selected because it involves carefully selecting potential participants who could provide insight into the lived experiences of asbestos-cement roofed houses (Kumar, 2014). The participants' inclusion criteria for this study were people residing in Phomolong who had lived in asbestos-cement roofed houses for over a year and were willing to partake in the study. Thus, inhabitants residing in Phomolong but staying in houses without asbestos-cement roofs and those who have lived in asbestos-cement-roofed houses for less than a year were excluded.

3.3 DATA COLLECTION METHOD

The semi-structured interviews with participants were conducted by the researcher visiting the study site during weekends to increase the chances of finding more participants at home who have time to spare for the interviews. When entering a potential participant's house, the researcher entered with a third party accompanying them to ensure their safety and permission to conduct an interview. If granted, the researcher and participant would then conduct the interview. The third-party accompanying the researcher would wait outside to ensure the confidentiality of the participant. The interviews with the participants were conducted in Sesotho, IsiXhosa, or English, depending on the participant's preference. The interviews started with the researchers formally introducing themselves to establish rapport and explaining the purpose and other information about the study. This included asking permission to record the interview and their willingness to partake. When participants agreed, the researcher asked them to sign the consent form. The researcher recorded the interviews. Each interview took about 20 to 30 minutes to complete. To anonymise and separate the different participants, the researcher allocated each participant a unique participant number, such as P1, P2, etc. The interview guides had three parts: the participants' demographic information, the challenges they experienced and the coping strategies to overcome them. In all, 11 participants were interviewed, and although the researcher reached saturation after conducting the 10th interview.

3.2 DATA ANALYSIS

The data analysis process within the qualitative approach is when the collected data is processed by organising, analysing, and interpreting the data (Johnson & Christensen, 2019). The data collected were analysed using the thematic content analysis approach. This analysis approach was chosen as it is an analysis that allows novice researchers to better understand how qualitative data analysis is conducted, with the vast literature available. In this analysis approach, the data were reduced, displayed, and then coded to identify emerging themes and create a narrative (Johnson & Christensen, 2019). The data was processed by translating and transcribing the interviews, familiarising the researcher with the data. This was done by reading through the transcriptions, identifying the initial patterns from the transcripts, and using the initial patterns to identify the main patterns. Similar themes were then grouped into themes and sub-themes. The Excel statistical tool was then used to calculate the frequencies and percentages of the participants' demographic data and formulate the theme items.

4. FINDINGS

4.1 DEMOGRAPHIC DATA OF PARTICIPANTS

The table presents the demographic data of the participants sampled. Male participants constitute 55% males and females 45%. Most participants (91%) have lived in the house for over 5 years. Most participants (73%) indicated that the asbestos cement roofs are over 30 years old. 82% of the participants' houses are owned by the participants' late parents or grandparents. 55% of the participants reside in four-roomed houses, whilst 45% reside in three-roomed houses. The employment analysis indicated that 55% were either unemployed or studying.

Table 1: Demographic factors of participants

Demographic factors		Number of participants	Percentages
Gender profile of participants	Male	6	55%
	Female	5	45%
	Total	**11**	**100%**
Number of years as a resident in the current house	Under 5 years	1	9%
	Between 5 and 30 years	3	27%
	Over 30 years	7	64%
	Total	**11**	**100%**
The estimated number of years the current roof has been used	Under 5 years	0	0%
	Between 5 and 30 years	3	27%
	Over 30 years	8	73%
	Total	**11**	**100%**
Ownership status of houses where participants live	Owned by late parent(s)/grandparent(s)	9	82%
	Renting	2	18%
	Total	**11**	**100%**
House Size where participants live	3 rooms	5	45%
	4 rooms	6	55%
	Total	**11**	**100%**
Employment status	Unemployed	4	36%
	Self/temporarily employed	3	27%
	Employed	2	18%
	Student	2	18%
	Total	**11**	**100%**

4.2 COPING STRATEGIES

Having identified the challenges faced by the participants, such as poor living conditions inside these houses, difficulty in maintaining the asbestos roof, removal and disposal difficulties and health concerns, they asked the participants to describe navigation

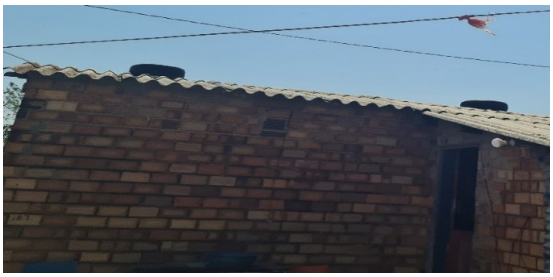
strategies to overcome their challenges with asbestos-cement roofed houses. The responses to the coping strategies were analysed to determine initial patterns, coded, and grouped into the different themes, as presented in Table 2. This table indicates three strategic coping mechanisms used by the participants, namely sealing and painting roofs inside, placing materials such as tyres and rocks on roofs and other intermediate strategies such as placing buckets when it rained and binding wires on walls to hold down the roofs.

Table 2: Participants' coping strategies for asbestos cement roof challenges

Main themes	Sub-themes
Placing material on the roof	Tyres and rocks
	Replacement sheet - asbestos or corrugated iron sheets
Sealing and painting the roof inside	Sealing holes from inside
	Painting the roof inside
Other strategies	Placing buckets
	Binding wire on walls

4.2.1 Theme 1: Placing Material on the Roof

The first strategic theme mentioned by the participants is placing materials on the roof when raining and providing support to roofs on windy days. Four participants placed tyres or rocks on their asbestos cement roofs. It was established that they do this as a preventative measure to prevent their roofs from getting blown away. During site visits, the researcher also noticed that this strategy was used in different asbestos-cement roofed houses in the neighbourhood. Depicting these strategies, Figure 1, picture A, illustrates two households where the material was placed on roofs to support the roof against the wind. The comments made by participants P1 and P10 also gave directions for their reasons for putting these on the roofs.



P10: *"... This is why we put tyres to secure the roofs from flying away",*

P1: *"To prevent it from going up we have placed rocks on top of roofs".*

Other participants indicated that they sourced replacement sheets of asbestos or corrugated iron sheets. They stated that the asbestos-containing cement material sheets could not be bought, so they sourced them from people who had removed their asbestos roofs. For example, P2 said the corrugated iron sheets are sourced second-hand or purchased at a building supply shop.

P2: "*If it gets a hole for example, you get another piece from someone else who has taken it out and close the space in your house"*

The sheets are replaced or placed on top/below the existing asbestos sheet. In most instances, these were installed near the chimney or where there were big holes in the sheet. For instance, Figure 1, picture B indicate houses where this strategy was used. Noticeably, they additionally place supportive material, in this case, rocks. The first image also illustrates where corrugated iron was added under the asbestos-containing roof, where the redundant chimney is located.

Picture A

Picture B

Figure 1: Pictures of an unsecured asbestos roof support against the wind

4.2.2 Theme 2: Sealing and Painting the Roof Inside

The second strategic theme discussed is sealing holes inside the roof to avoid stepping on the asbestos cement roof, which breaks easily and paints to enhance its appearance, minimise dust and temporarily make sealant stick on the roof. Eight participants stated they tried to seal holes from the inside. While most use this strategy, it is temporary and sometimes used as a minimisation strategy instead of prevention. It is a minimisation strategy because it may not completely prevent water from coming in, as the hole would still be visible from the outside. Still, it would decrease the amount of water drips into the house compared to when it is left unsealed. This strategy was seen in Figure 2, picture D, where the participants used sealants such as silver waterproof tape and multipurpose glue. This indicates its fragility, and the only condition people are willing to seal it. Some participants indicated they painted their roofs inside. They, however, had different reasons for painting them. An example is in Figure 2, picture C, where the participant painted it to make it look better.

P4: *"We paint it to get rid of the water stains".*

P11: *"After patching it, I paint it to try and keep it glued to the roof".*

Picture C: Dusty roof painted over

Picture D: Dusty roof painted over

Figure 2: Pictures of a painted asbestos roof to improve its aesthetics.

For instance, P5 indicated that it is difficult to wash the roof; thus, they painted it to improve the colour, which subsequently peeled off. Additionally, P11 stated that it becomes a bit better when you apply water paint. One participant, P7, said he had painted it a while back and would only be repainting it. His rationale for this is based on the idea that the roofs may be removed any day, and he is worried he would have wasted his money if he painted it today and it gets removed soon after.

P5: *"You see also with the paint; over time it gets removed".*

P7: "*I painted it a while back and did not after as they had said they would remove them. So, I will paint it today and tomorrow they come and remove it while I spent my money to buy the paint".*

4.2.3 Theme 3: Other Coping Strategies

Participants indicated other strategies they use besides those discussed in the previous sections. These were to place buckets where roofs leak and add binding wires on the walls to support the poles and roof during windy days. Six participants stated they place buckets inside their houses when rainwater drips to prevent their furniture from getting wet and the house from getting messy. While no images were acquired indicating the buckets being used, some participants pointed out places where water drips typically when it rains. For example, P6 pointed out the holes and suggested that they place buckets in those areas during rainfall.

P6: *"Here we have holes; we just put a bucket in most cases"*

Figure 3, picture E, illustrates some of the areas where buckets are used to collect the water from the roof during rain, as pointed out by the participants.

Picture E Picture F

Figure 3: Pictures of a leaking asbestos roof where buckets collect the water during rainfall, and binding wires are installed to the external walls to hold the roof structure.

The other strategy for the participants' houses was to install binding wires around the external walls attached to the roofing poles. Four participants stated this strategy, and the researcher observed this during the site visits. For instance, P1, in explaining why they had installed these, noted that the father installed the binding wires.

P1: *"My dad before he passed added binding wires to hold the poles down - this has been an issue for ages now".*

Figure 3, picture F, illustrate different participants' houses where this strategy was observed.

5. DISCUSSION

The inhabitants of asbestos-cement roofed houses used six coping strategies in Phomolong; none of these were cited in academic literature. The identified coping strategies were used to minimise the challenges related to dust, wind, rain, and physical damage to roof sheets. This study did not identify the coping strategies that Obminski (2022) posited, such as having good ventilation for air exchange and decreasing the concentration of asbestos dust inside a building. The physical conditions and limited finances may have limited this strategy's use. For example, changing the standard windows to add bigger ones would require the participants to have money to buy the

windows and get them fitted. Additionally, observed cracks on the structural walls could be another limiting factor in why this strategy is not used there. Gibson et al. (2021) state that communities have and will continue to live with asbestos cement roofs for decades. The findings of this study support and provide evidence for this notion. It was observed that most participants (64%) have lived in these houses for over thirty years and recall these houses being older than that. Additionally, considering the challenges identified, inhabitants of asbestos-cement roofed houses in Phomolong have been forced to adopt coping strategies. Kottek and Yuen (2021) state that although asbestos removal is ongoing, inhabitants devise several means of dealing with the current challenges. These coping strategies are used to minimise the challenges related to dust, wind, rain, and physical damage to roof sheets. Bonifazi et al. (2018) suggest that, because of the status of many asbestos roof houses, serious intentions must be made by the authorities to address the inhabitants' challenges. Gil et al. (2024) identified that many asbestos roof covering conditions were hazardous to the inhabitants; they used several means to contain the dilapidated state. This, they indicate, was a great concern for the community. Likewise, Martínez et al. (2024) identified that several people's strategies for controlling their asbestos roofs were insufficient; they proposed that authorities identify the state of the various roofs and develop prioritised intervention strategies to mitigate the problem. In support of this, Saba et al. (2024) posit that roofing materials also play a significant role, with thermoacoustic roofs reducing emissions compared to asbestos cement roofs. These concerns confirm the findings of this study, where people need an urgent intervention from the government to address their concerns about the asbestos roof. Authorities must ensure that replacing asbestos cement roofs with the urgency it deserves to address inefficient practices adopted by the inhabitants, which more often pose a health risk to them.

6. IMPLICATION OF THE FINDINGS

The findings show that the government policy on removing asbestos cement roof houses in legacy townships, like the case study town in South Africa, has failed to achieve its goal. Thus, posing a health-related risk to the inhabitants of these houses and the communities at large. The study also identified during the site visit that many community members are still using asbestos to construct informal houses and fences around their houses, oblivious of the danger it poses to their health. This calls for the government to intensify the public health education within these communities and address the elimination of asbestos roof policy with more urgency.

7. CONCLUSION AND RECOMMENDATION

Over a decade ago, the South African government embarked on a programme to remove asbestos roofing from all the legacy township houses. However, this attempt has not been materialised, with many houses in rural areas having dilapidated asbestos roofs posing danger and maintenance challenges to the inhabitants. Considering the environmental risk to society and communities, this asbestos roof removal must be done. As such, these inhabitants cannot remove them unless the government agency responsible for this task executes the removal in compliance with the environmental regulations. The study, therefore, sought to explore the lived experiences of the inhabitants of asbestos-roofed houses to bring their ordeal to policymakers so that they could revisit perhaps the asbestos removal programme abandoned over the years. The study identified many challenges the

inhabitants face, including health, poor living conditions, and maintenance issues. To overcome these challenges, they apply several strategies, including placing material on the roof, sealing and painting the roof inside and other strategies. This situation poses health risks to the inhabitants, especially during the winter and rainy seasons. The study, therefore, recommends urgent government interventions to remove these roofing materials to ensure healthy living conditions for the inhabitants. The government can also engage with private organisations to promptly facilitate the removal of roofing. The government can also engage non-governmental organisations to assist these inhabitants in removing the asbestos roof and replacing it with the appropriate roofing materials. The community councillors must agitate and draw the urgency of this asbestos roof phenomenon to the government and other municipal leaders to ensure the problem is resolved. The limitation of the study is that a case study approach for a specific setting, thus the findings may not be generalised. Future studies must examine the challenges of the government in executing the asbestos roof removal programme since its inception, which has led to several communities still having these roofs on their houses.

CRITERIA FOR SELECTING RETROFITTING OPTIONS FOR HVAC SYSTEMS IN SRI LANKAN COMMERCIAL BUILDINGS

G.N.T.J. Bandara[1], Sachie Gunatilake[2] and Dasuni Kodituwakku[3]

ABSTRACT

The heating, ventilation, and air conditioning (HVAC) systems are among the largest consumers of energy within buildings, constituting about 51% of the overall energy consumption. Thus, implementing energy retrofit measures can yield a noteworthy reduction in energy consumption of buildings. However, the process of selecting suitable energy retrofit options is complex and requires consideration of numerous different criteria. This research aims to propose a comprehensive set of evaluation criteria relevant to the selection of HVAC retrofitting options for commercial buildings in Sri Lanka. Through a thorough literature review and expert interviews with respondents selected using purposive sampling in which the collected data were analysed using manual content analysis, 35 sub-criteria that should be considered when selecting HVAC retrofitting options for commercial buildings in Sri Lanka were identified. These were categorised under 07 main criteria as Economic factors, Technical properties, Physical properties, Flexibility, Reliability, Comfortability and Environmental aspects. Thus, the findings mark the first step in developing a structured approach for evaluating and selecting HVAC retrofit options, streamlining decision-making processes, and potentially leading to more efficient and cost-effective building upgrades.

Keywords: *Commercial Buildings; Evaluation Criteria; Heating, Ventilation, and Air Conditioning (HVAC) Systems; Retrofit Options.*

1. INTRODUCTION

The construction industry significantly contributes to global energy consumption (Madushika et al., 2023). Buildings alone account for about 36% of global final energy use and nearly 40% of total direct and indirect CO_2 emissions (Y. Wang et al., 2022). Both residential and commercial buildings demand substantial energy for heating, cooling, lighting, and operating various equipment and systems (Hong et al., 2015). Therefore, building energy efficiency retrofits are considered essential for achieving energy reduction and sustainable development goals (X. Liang et al., 2015).

[1] Undergraduate, Department of Building Economics, University of Moratuwa, Sri Lanka, nilankathushara1998@gmail.com
[2] Senior Lecturer, Department of Building Economics, University of Moratuwa, Sri Lanka, sachieg@uom.lk
[3] Lecturer, Department of Building Economics, University of Moratuwa, Sri Lanka, ldasuni@uom.lk

The heating, ventilation, and air conditioning (HVAC) systems are among the largest consumers of energy within buildings, constituting about 47% of the overall energy consumption (Hong et al., 2015). In parallel, lighting accounts for approximately 25% of total energy usage (Dolšak, 2023). Specific components like vertical transportation, pumps, and related equipment collectively represent around 5-10% each. The cumulative effect of HVAC and lighting system energy usage typically constitutes around three-quarters of the aggregate energy demand for buildings (Y. Wang et al., 2022).

Retrofitting refers to the process of adding new technology or features to existing systems that were not present during their initial construction phase (J. Liang et al., 2018). This is particularly relevant in the context of HVAC systems in commercial buildings, where the goal is to enhance energy efficiency, reduce operational costs, and minimize maintenance expenses. This process aims to curb energy consumption and advance energy efficiency enhancements (Fasna & Gunatilake, 2019). Retrofitting projects for existing HVAC systems aim to address inefficiencies and integrate advanced technologies to enhance performance (Ligade & Razban, 2019). Common retrofit measures include upgrading to energy-efficient components, implementing advanced control strategies, and optimizing system operation through continuous monitoring and diagnostics (C. Liu et al., 2023).

The process of selecting suitable energy retrofit options is complex and requires a well-organised, step-by-step approach (Ma et al., 2012). For instance, Krajčík et al. (2023) has highlighted the need for a comprehensive retrofit evaluation encompassing economic, risk, social, environmental, and health impact assessments. However, despite the benefits of HVAC retrofitting, there is a lack of comprehensive guidelines and frameworks for implementing these projects effectively (Amanda & Sanjei, 2019). This is particularly pertinent in the context of Sri Lanka, where the commercial building sector faces unique challenges in implementing retrofit projects. Local climatic conditions, building designs, and occupancy patterns must be carefully considered to ensure the success of retrofit initiatives (De Silva & Sandanayake, 2012). Additionally, local environmental regulations and energy policies play a crucial role in shaping retrofit strategies.

Despite the recognised benefits, the process of selecting appropriate retrofit options is complex and often lacks a standardised framework, particularly in developing countries such as Sri Lanka. Hence, this research aims to propose a comprehensive set of evaluation criteria relevant to the selection of HVAC retrofitting options for commercial buildings in Sri Lanka. The findings of this study provide the basis for developing a structured decision-making framework for selecting HVAC retrofitting options for Sri Lankan commercial buildings using multi-criteria decision making.

2. LITERATURE REVIEW

2.1 ENERGY CONSUMPTION IN BUILDINGS

Heating, Ventilation, and Air Conditioning (HVAC) systems are critical components in buildings, significantly impacting their overall energy consumption (Hong et al., 2015). HVAC systems are responsible for approximately 39% of the total energy consumption in commercial buildings (Nalley & LaRose, 2022). This substantial proportion underscores the importance of HVAC systems in the broader context of building energy management. The efficiency of HVAC systems is vital not only for reducing energy consumption but also for maintaining indoor air quality and thermal comfort, which are essential for occupant health and productivity (Ma et al., 2012). Despite their importance,

many existing HVAC systems are outdated and operate inefficiently, leading to high energy usage and increased operational costs (Ligade & Razban, 2019). Additionally, maintenance costs for HVAC systems can be substantial, further adding to the operational expenses of commercial buildings (Y. Wang et al., 2022). Consequently, improving HVAC system efficiency is a critical focus area for reducing building energy consumption and associated costs.

In the Sri Lankan context as well, the energy consumption in commercial buildings is notably high, primarily due to the extensive use of HVAC systems, which can represent up to 60% of a building's total energy consumption (Kumar & Raposa, 2020). This high percentage underscores the critical need for energy-efficient retrofitting solutions to reduce energy consumption and operational costs. Urban commercial buildings in Sri Lanka rely heavily on HVAC systems for cooling and ventilation, resulting in substantial energy demands (Kumar & Raposa, 2020). By implementing energy-efficient HVAC retrofits, these buildings can achieve significant energy savings, contributing to the country's overall energy efficiency goals.

2.2 HVAC SYSTEMS IN SRI LANKAN COMMERCIAL BUILDINGS

Commercial buildings are structures primarily used for business activities, including offices, retail spaces, hotels, and educational institutions (Hong et al., 2015). These buildings significantly contribute to energy consumption due to their extensive use of lighting, heating, ventilation, and air conditioning (HVAC) systems. In the Sri Lankan context, commercial buildings are typically concentrated in urban areas such as Colombo, Kandy, and Galle, where the demand for energy is high to maintain comfortable indoor environments (Sustainable Energy Authority of Sri Lanka, 2020).

Given Sri Lanka's tropical climate, air cooling systems are essential, whereas heating systems are seldom used. The country experiences high temperatures and humidity levels throughout the year, making cooling systems critical for occupant comfort. Districts such as Colombo and Gampaha, which are highly urbanized and densely populated, rely heavily on air conditioning systems to provide a comfortable indoor climate (Sustainable Energy Authority of Sri Lanka, 2020). This necessity underscores the importance of efficient HVAC systems in these regions. Retrofitting such systems can involve upgrading components to more energy-efficient models, integrating advanced control systems, and optimizing the overall system performance to reduce energy consumption (Madushika et al., 2023). This process not only enhances the efficiency but also extends the lifespan of the HVAC systems.

2.3 RETROFITTING HVAC SYSTEMS

Existing HVAC systems, particularly package units, often face numerous issues as they age. Common defects include reduced efficiency, frequent breakdowns, and increased operational costs due to wear and tear (Karunaratne & De Silva, 2019). After five years, systems typically begin to show signs of inefficiency, and by ten to fifteen years, the frequency of repairs and maintenance increases significantly, often leading to higher energy consumption and operational disruptions. Retrofitting offers a viable solution to these identified defects (Ligade & Razban, 2019).

Retrofitting involves the process of adding new technology or features to existing buildings to improve their functionality, efficiency, and sustainability (Ebrahimi et al.,

2023). Building retrofits can encompass various aspects, including structural, energy, and aesthetic improvements. Energy retrofits, a subset of retrofitting, specifically focus on enhancing the energy performance of buildings to reduce energy consumption and operational costs (Y. Liu et al., 2023).

Building retrofits are particularly important in commercial buildings, where energy consumption is significantly high due to extensive use of HVAC systems, lighting, and other equipment (Mohamed & Wang, 2020). The major advantages of retrofitting over other methods, such as complete system replacement, include cost-effectiveness and minimized disruption to building operations. Retrofitting allows for incremental improvements without the need for extensive downtime, making it a practical option for commercial buildings that cannot afford long periods of inactivity (Karunaratne & De Silva, 2019). Moreover, retrofitting enhances the sustainability of buildings by reducing energy consumption and greenhouse gas emissions, contributing to broader environmental goals.

Retrofitting in commercial buildings can lead to substantial energy savings by implementing advanced technologies and optimizing energy management systems (Hong et al., 2015). For instance, upgrading to high-efficiency HVAC systems can drastically reduce energy usage, while smart building technologies can further enhance energy efficiency by optimizing the operation of various systems within the building (C. Liu et al., 2023).

HVAC retrofitting typically encompasses several measures, including upgrading HVAC equipment, improving insulation and sealing, and implementing advanced control systems (Bird et al., 2022). Notably, these measures aim to enhance the energy performance of the building while ensuring occupant comfort. This often yields long-term benefits by reducing energy costs and carbon footprints (Ma et al., 2012). By upgrading components such as compressors, fans, and control systems, the efficiency of aging HVAC systems can be significantly improved. Additionally, retrofitting can involve implementing advanced monitoring and control systems that optimize the operation of HVAC units, thereby reducing energy consumption and enhancing performance (Madushika et al., 2023). For instance, replacing old, inefficient chillers with high-efficiency models can result in substantial energy savings and improved reliability. The process of selecting suitable energy retrofit options is complex and requires consideration of numerous criteria that may change depending on the context. Hence, there is a need to clearly identify a set of evaluation criteria relevant to the selection of HVAC retrofitting options for commercial buildings in Sri Lanka.

3. RESEARCH METHODOLOGY

A comprehensive literature review was conducted to identify the evaluation criteria for HVAC retrofit options. The search was carried out in databases such as Science Direct, Web of Science, and Scopus, and included keywords such as “retrofit”, “energy efficiency”, “criteria”, and “evaluation”. The search was limited to the papers published in the 20 year period between 2005 and 2024. Altogether, 56 journal papers were selected for the identification of criteria through the above systematic selection process. Then, interviews with three industry experts were conducted to refine and confirm the relevance and importance of each identified criterion, ensuring that they would be grounded in practical and expert knowledge. The small sample helped to facilitate researchers’ close

association with the respondents and allowed fine-grained, in-depth interviews (each interview lasted for over 60 minutes) to be carried out on the selection criteria. Further, the selected respondents could be considered as experts in the research area possessing over 15 years of first-hand experience in HVAC retrofitting. Table 1 presents profile of the three experts interviewed.

The expert interviews were conducted as semi-structured interviews with an iterative and interactive process. The interviews were carried out in an iterative process with each expert's views been considered by the others. The first expert's decision was communicated to the second expert, facilitating a more comprehensive discussion and a refined consensus. Subsequently, during the interview with the third expert, the previous experts' opinions were presented to provide context and foster a deeper dialogue. The final decision was reached through a rigorous analysis of all three expert perspectives, coupled with a synthesis of existing knowledge from the literature. This allowed for a detailed review of the criteria and their application to the local context. Manual content analysis was used to analyse both the literature review and interview data to identify the evaluation criteria. The findings presented in this paper mark the first step in a broader research study aimed at developing a structured decision-making framework for selecting HVAC retrofitting options for Sri Lankan commercial buildings using multi-criteria decision making.

Table 1: Profile of interview respondents

Respondent	Designation	Current Sector	Experience (Years)	Qualifications		Awareness	
				Educational	Professional	HVAC	Retrofit
R1	Director (Facility Manager)	Consultant	30	M.FM, BSc. Eng	Chartered FM	Well	Well
R2	Manager (Facility Manager)	Contractor	15	BSc FM, Dip in Arb.	Chartered FM	Well	Well
R3	Manager (Engineer)	Contractor, Lecturer	33	PhD, M.Eng, BSc Eng	Chartered Engineer	Well	Aware

4. FINDINGS AND DISCUSSION

4.1 OVERVIEW OF RETROFITTING HVAC SYSTEMS IN SRI LANKAN COMMERCIAL BUILDINGS: FINDINGS FROM EXPERT INTERVIEWS

Retrofitting commercial buildings involves enhancing energy efficiency and operational performance through various methods. Experts generally agree on the significance of this practice, albeit with nuanced perspectives. For instance, R1 described retrofitting as upgrading existing systems to modern standards, focusing on energy efficiency. Similarly, R3 emphasised the addition of new components to boost energy performance, while R2 pointed out the replacement of outdated systems. Collectively, these views

underline retrofitting as a comprehensive approach aimed at modernisation and energy optimisation.

Regarding HVAC systems in Sri Lankan commercial buildings, a clear preference for package systems in light commercial buildings is evident. R1 and R2 mention the use of water-cooled package systems due to their balance of cost and efficiency.

4.2 CRITERIA FOR SELECTING HVAC OPTIONS

Table 2 summarises key criteria identified from literature that should be considered when selecting HVAC retrofitting options. These criteria highlight the essential factors that can influence the success and effectiveness of such projects.

Table 2: Criteria for selecting HVAC options: Findings from literature review

Criteria/Sub-criteria	Sources	Description
Economic Factors		
Capital Cost	[5] [6] [15] [16]	Initial expenditure required to implement a retrofit project
Maintenance Cost	[5] [6] [15] [16] [17]	Ongoing expenses for the upkeep of the retrofitted system
Operational cost	[5] [6] [12] [19] [21]	Day-to-day expenses involved in running the retrofitted systems
Payback Period	[5] [6] [12] [14] [18]	The time it takes for the investment in retrofitting to be recovered through cost savings
Life-Cycle Cost (LCC)	[5] [6] [15] [16] [18]	Total cost of owning, operating, and maintaining a building system over its entire life span
Insurance cost	[9]	Expenses related to insuring the retrofitted systems
Technical Properties		
Water Consumption	[18] [19]	The amount of water used by the HVAC system
Energy Consumption	[5] [6] [12]	The total energy used by the HVAC system
CO2 emission	[5] [12] [15] [20]	The amount of CO2 produced by the HVAC system
Refrigeration coefficient	[18] [19]	Efficiency measure of the refrigeration cycle in HVAC systems
COP (Coefficient of Performance)	[21] [22] [23]	A ratio that measures the efficiency of HVAC systems
Humidity control	[5] [6] [7] [8]	The system's ability to regulate indoor humidity levels
Physical Properties		
Area requirement	[5] [6] [12]	Space needed to install and operate HVAC systems
Indoor Appearance	[25] [26]	The aesthetic impact of HVAC systems within the building interior
Outdoor Appearance	[25] [26] [27] [28] [29]	The visual impact of HVAC systems on the building's exterior

Criteria/Sub-criteria	Sources	Description
Loss of usable floor space	[5] [6] [12]	Space that becomes unusable due to the installation of HVAC systems
Noise level	[5] [6] [12]	The amount of noise generated by the HVAC systems
Flexibility		
Installation flexibility	[5] [6] [30] [31] [32] [33]	Ease of installing retrofit systems in existing buildings
Integration flexibility	[5] [6] [30] [31] [32] [33] [34] [35]	Ability of new systems to integrate with existing infrastructure
Ease of maintenance	[35] [40] [41] [42] [43]	Simplicity and convenience of maintaining the retrofitted systems
Future flexibility	[36] [37] [38] [39]	Capacity for future expansions or modifications
Reliability		
Lifetime	[5] [6] [12] [41] [44] [45] [46]	Expected operational life span of the retrofitted system
Lead time	[5] [6] [12] [47] [48]	Time required to implement the retrofit
Repair time	[5] [6] [47] [48] [49]	Time required to fix issues in the retrofitted systems
Vendor availability	[15] [50]	Accessibility of suppliers and maintenance services for the retrofitted systems
Comfortability		
Degree of compatibility	[1] [2] [3] [4] [5]	How well the retrofitted system integrates with the existing building infrastructure
Occupants' health and safety	[5] [6] [9] [10]	Impact of HVAC systems on the well-being and safety of building occupants
Thermal comfort	[13] [14]	The ability of HVAC systems to maintain comfortable temperature and humidity levels
Cleanliness	[13] [14]	The system's ability to maintain a clean indoor environment

The literature review identified altogether 31 sub-criteria that should be considered in selecting HVAC options. These 31 sub-criteria were categorized under 06 main criteria as given in Table 2. These criteria and sub-criteria were then refined and checked for relevance and importance to the study context through the expert interviews.

In instances where all three experts reached a consensus on accepting or rejecting a given criterion, the final decision was made accordingly. However, in cases where there was a single dissenting opinion, careful consideration was given to the differing perspectives, alongside a thorough examination of relevant literature, before a final determination was made. If only one expert rejected a criterion, it was kept, as the other two experts provided good reasons for its inclusion. These decisions were also supported by information found in existing research. The goal was to create a clear and comprehensive set of criteria for evaluating HVAC systems relevant to the local context that everyone could understand.

Table 3 provides the findings of the expert interviews in relation to the above.

Table 3: Criteria for selecting HVAC options: Findings from expert interviews

Criteria/Sub-criteria	Interviewee			Decision
	R1	R2	R3	
Economic Factors				
Capital cost	Accepted: Critical for initial capital budget assessment	Accepted: Fundamental for financial feasibility studies	Accepted: Essential for upfront cost evaluation	✓
Maintenance cost	Accepted: Influences lifecycle operating expenses	Accepted: Integral to total cost of ownership	Accepted: Affects long-term sustainability	✓
Operational cost	Accepted: Impacts ongoing operational efficiency	Accepted: Vital for energy expense management	Rejected: Variability challenges in cost prediction	✓
Payback period	Accepted: Key for evaluating return on investment	Rejected: Difficulties in accurate financial forecasting	Accepted: Important for financial justification	✓
Life-Cycle Cost (LCC)	Accepted: Crucial for overall cost-benefit analysis	Accepted: Core to comprehensive cost management	Accepted: Essential for total cost considerations over time	✓
Insurance cost	Accepted: Not pivotal for technical retrofit decision-making	Accepted: Minimally impacts project viability	Accepted: Irrelevant to core retrofitting parameters	✓
Technical Properties				
Water consumption	Moved: Peripheral to core HVAC functions	Moved: Insignificant impact on system performance	Moved: Relevant in specific environmental compliance cases	

Criteria/Sub-criteria	Interviewee			Decision
	R1	R2	R3	
Energy consumption	Accepted: Directly correlates with system efficiency	Accepted: Critical for reducing energy costs	Accepted: Fundamental to operational performance	✓
CO_2 emission	Rejected: Lesser immediate retrofit impact	Accepted: Important for environmental sustainability	Accepted: Crucial for regulatory compliance	✓
Refrigeration coefficient	Accepted: Relevant for cooling systems' efficiency	Rejected: Limited applicability outside specific contexts	Rejected: Not widely applicable across HVAC systems	×
COP (Coefficient of Performance)	Accepted: Indicates system performance efficiency	Accepted: Benchmark for energy performance	Accepted: Standard measure of system efficiency	✓
Humidity control	Accepted: Critical for indoor air quality and comfort	Rejected: Region-specific importance	Accepted: Essential for maintaining occupant comfort	✓
Degree of compatibility		Moved: new upgrades should match the existing system	Moved: Include compatibility as a key criterion in your evaluation framework for retrofitting options	+
Physical Properties				
Area requirement	Accepted: Essential for system integration within space	Accepted: Important for retrofit space planning	Rejected: Retrofit should adapt to existing spatial constraints	✓
Indoor appearance	Accepted: Influences occupant perception and satisfaction	Accepted: Affects aesthetics and user experience	Accepted: Enhances interior environmental quality	✓
Outdoor appearance	Accepted: Impacts external aesthetics and compliance	Accepted: Important for building facade integration	Accepted: Vital for architectural harmony	✓
Loss of usable floor space	Rejected: Already consider that as "Area Requirement"	Rejected: Overlap with “Area Requirement"	Rejected: Better consider Area requirement	×
Noise level	Accepted: Crucial for ensuring acoustic comfort	Accepted: Integral to environmental comfort standards	Accepted: Reduces noise pollution and enhances usability	✓
Flexibility				
Installation flexibility	Accepted: Facilitates integration into existing structures	Accepted: Reduces installation complexities	Accepted: Enhances adaptability to building layouts	✓

Criteria/Sub-criteria	Interviewee			Decision
	R1	R2	R3	
Integration flexibility	Accepted: Ensures seamless system integration	Accepted: Promotes compatibility with existing infrastructure	Accepted: Critical for comprehensive retrofit solutions	✓
Ease of maintenance	Accepted: Simplifies maintenance, reducing lifecycle costs	Accepted: Decreases operational disruptions	Accepted: Essential for ongoing system reliability	✓
Future flexibility	Accepted: Allows for future technological upgrades	Accepted: Essential for scalable retrofit solutions	Accepted: Facilitates future system enhancements	✓
Energy source flexibility	Accepted: Adapts to diverse energy inputs	Accepted: Supports sustainable energy transitions	Accepted: Enables flexibility in energy sourcing	✓
Reliability				
Lifetime	Accepted: Indicates durability and long-term serviceability	Accepted: Reduces frequency of replacements	Accepted: Ensures long-term operational stability	✓
Lead time	Accepted: Affects project timeline and resource allocation	Accepted: Important for scheduling and logistics	Accepted: Critical for timely project execution	✓
Repair time	Accepted: Minimizes downtime, enhancing operational continuity	Accepted: Reduces maintenance impact on operations	Accepted: Vital for quick recovery and serviceability	✓
Vendor availability	Accepted: Ensures access to essential parts and services	Accepted: Facilitates reliable maintenance and upgrades	Accepted: Critical for continuous system support	✓
Comfortability				
Occupants' health and safety	Accepted: Directly impacts well-being and regulatory standards	Accepted: Fundamental to occupant safety	Accepted: Ensures compliance with health codes	✓
Thermal comfort	Accepted: Affects energy efficiency and occupant comfort	Accepted: Integral to environmental control	Accepted: Essential for maintaining optimal indoor climates	✓
Cleanliness	Accepted: Impacts air quality and cleanliness	Accepted: Integral to maintaining hygienic conditions	Accepted: Essential for occupant health and satisfaction	✓
Environmental Aspects				
Carbon emissions	Moved: Aligns with global sustainability goals	Moved: Essential for environmental stewardship	Moved: Critical for meeting modern environmental standards	+

Criteria/Sub-criteria	Interviewee			Decision
	R1	R2	R3	
Water consumption		Moved: Important for water conservation	Moved: Aligns with eco-friendly practices	+
Type of refrigerant	Added: Affects global warming potential and ozone depletion		Added: Critical for environmental compliance	+
Renewable energy sources		Added: Facilitates transition to greener energy sources	Added: Essential for sustainable energy integration	+
Waste management	Added: Enhances sustainability and reduces retrofit impact	Added: Vital for minimizing environmental footprint	Added: Integral to eco-friendly retrofit practices	+

The experts agreed to move "Water Consumption," "CO_2 Emission," and "Refrigeration Coefficient" from the "Technical Properties" category to the "Environmental Aspects" category. This change better reflected the environmental impact of these factors. "CO_2 Emission" was renamed "Carbon Emission" for clarity. Expert R2 suggested adding a new criterion, "Degree of Compatibility," under "Technical Properties," which expert R3 also agreed with. If two out of the three experts rejected a criterion, it was removed. For example, "Loss of Usable Floor Space" was removed because it was considered similar to "Area Requirement," which was already included. Similarly, “Refrigeration Coefficient” was also removed as this was not widely applicable across HVAC systems. Figure 1 provides the finalised evaluation criteria for selecting HVAC options.

Economic Factors (E) **E1** Capital Cost **E2** Maintenance Cost **E3** Operational cost **E4** Payback Period **E5** Life-Cycle Cost (LCC) **E6** Insurance cost	**Technical Properties (T)** **T1** Water Consumption **T2** Energy Consumption **T3** CO_2 Emission **T4** Refrigeration coefficient **T5** COP (Coefficient of Performance) **T6** Humidity control **T7** Degree of compatibility

Figure 1: Finalised evaluation criteria for selecting HVAC options

Experts highlighted that the key stakeholders' preferences in the retrofit process reflect a focus on cost-effectiveness, energy savings, and feasibility. R1 and R2 emphasized the importance of financial feasibility and quick returns on investment (ROI), with R3 highlighting the role of cost savings and brand value in driving decisions. Experts also noted that high energy costs often prompt retrofit initiatives. Further, the importance of regulatory compliance and environmental impact was also highlighted. These perspectives reveal that stakeholders prioritise solutions offering economic and environmental benefits, aiming for operational efficiency and sustainability in retrofit projects. Economic incentives, such as reduced operational costs and increased property values, play a crucial role in driving retrofit decisions. Environmental motivators are also significant, with a strong focus on reducing energy consumption and carbon emissions, aligning with global sustainability targets. Additionally, technical improvements through retrofitting can increase the functional performance and safety of buildings, addressing the growing concern over natural disasters in the region (Ranawaka & Mallawaarachchi, 2018). These key motivators collectively support a comprehensive approach to building retrofitting in Sri Lanka, emphasizing the importance of integrated strategies that cater to economic efficiency and environmental responsibility.

Thus, expert opinions converge on the critical role of retrofitting in enhancing the energy efficiency and operational performance of Sri Lanka's commercial buildings. The preference for package systems in light commercial buildings is driven by their cost-effectiveness and efficiency. Stakeholders' decisions are guided by a balance of financial feasibility, energy savings, and regulatory compliance, ensuring that retrofitting efforts yield both economic and environmental advantages. The comprehensive insights from these experts provide a robust understanding of the strategies and preferences that shape retrofitting initiatives in the region.

5. CONCLUSIONS

This paper identified a set of evaluation criteria relevant to the selection of HVAC retrofitting options for commercial buildings in Sri Lanka. Altogether, 35 sub-criteria were identified. These were categorised under 07 main criteria as Economic factors, Technical properties, Physical properties, Flexibility, Reliability, Comfortability and Environmental aspects. Findings highlighted that the stakeholders' decisions are often guided by a balance of financial feasibility, energy savings, and regulatory compliance, ensuring that retrofitting efforts yield both economic and environmental advantages. Further, research is required to assign weightages to the identified criteria so that a comprehensive decision support criterion could be developed for evaluating and selecting retrofit options. This will in turn streamline the decision-making processes, potentially leading to more efficient and cost-effective building upgrades.

CROWDFUNDING FOR POST-DISASTER RECONSTRUCTION PROJECTS: A CONCEPTUAL FRAMEWORK

M.R.M. Riskan[1], K.D. Sepalage[2], D Weerasooriya[3] and K.A.T.O. Ranadewa[4]

ABSTRACT

Post-Disaster Reconstruction (PDR) projects are essential for rebuilding communities affected by natural disasters and conflicts. Despite the increasing global demand, their success is often hindered by economic, social, and physical challenges. Among the economic constraints, insufficient funding is a critical barrier due to the substantial financial requirements involved. Therefore, this study aimed to review available financial mechanisms for PDR projects and to explore the feasibility of crowdfunding for PDR projects. Accordingly, a comprehensive literature review was conducted on existing studies related to financial mechanisms and the application of crowdfunding for PDR projects. The content analysis method was used to analyse the collected data. The findings identified challenges in existing financial mechanisms such as inadequate funding, high transactional costs, time delays, upfront payments and bureaucratic processes. Overcoming these challenges, the study identified crowdfunding as a viable and innovative solution to attract additional financial resources. Crowdfunding enables the collection of small funds from a broader community, providing an inclusive and accessible financing option. Hence, this study contributes to academic and practical knowledge by bridging the concepts of crowdfunding and post-disaster reconstruction. Beyond its theoretical value, the study offers significant social and economic contributions by promoting inclusive, community-driven financing approaches that enhance resilience and recovery. Furthermore, it supports the achievement of the United Nations Sustainable Development Goals (SDGs), particularly SDG 11 (Sustainable Cities and Communities), SDG 9 (Industry, Innovation and Infrastructure), and SDG 17 (Partnerships for the Goals), by fostering sustainable, innovative, and collaborative reconstruction efforts.

Keywords: *Crowdfunding; Financial Architecture; Financing Methods; Funding Mechanisms; Post Disaster Reconstruction (PDR)*

1. INTRODUCTION

PDR projects play a critical role in restoring affected infrastructure and livelihood (Pamidimukkalla et al., 2020). According to Ismail et al. (2014), PDR projects refer to

[1] Graduate, Department of Building Economics, University of Moratuwa, Sri Lanka, riskanrizvan@gmail.com
[2] Lecturer, Department of Building Economics, University of Moratuwa, Sri Lanka, sepalagekd.19@uom.lk
[3] PhD Researcher, RMIT University, Australia, S4113999@student.rmit.edu.au
[4] Senior Lecturer, Department of Building Economics, University of Moratuwa, Sri Lanka, tharushar@uom.lk

the modification or complete replacement of a facility that has been completely or partially destroyed due to a catastrophic incident or disaster. Key components of PDR projects include damage assessment, reconstruction planning, community engagement, funding acquisition, construction management, and the implementation of more robust structural designs. In the Sri Lankan context, Siriwardhana and Kulatunga (2023) note that the country has placed considerable emphasis on PDR programs in response to the growing incidence of disasters.

PDR projects differ significantly from conventional construction projects due to their complexity, dynamism, and context-specific sociocultural and economic demands (Shafique & Warren, 2016). Despite support from governments, NGOs, and aid agencies, their success rate remains low due to implementation challenges (Ismail et al., 2014). Key issues include cost overruns from project delays and inefficient material use (Syaputra & Rarasati, 2023), as well as limited financial resources (Pamidimukkalla et al., 2020). Predominantly donor-driven, PDR projects rely on loans and aid, with limited private investment due to their non-profitable nature. In Sri Lanka, Nissanka (2008) identify Donor-Driven and Owner-Driven approaches in housing reconstruction, noting that many non-profits lack structured financial mechanisms for sustainable funding.

Due to limited access to conventional external financing, many entrepreneurs have increasingly turned to alternative funding sources, with crowdfunding emerging as a prominent and effective method (Hoque, 2024; Schwienbacher & Larralde, 2010; Mollick, 2014). Crowdfunding enables individuals to raise capital through small contributions from a large number of supporters via online platforms, bypassing traditional investment channels (Syaputra & Rarasati, 2023). Latorre (2016) highlights the growing application of crowdfunding in the construction industry, particularly in housing and real estate development. While several studies have explored its potential in construction financing, the use of crowdfunding specifically for PDR projects remains under-researched, and evidence of its successful implementation is limited.

Despite the potential for growth, social crowdfunding platforms have seen limited development, primarily due to investment constraints and concerns regarding transparency, reliability, and trustworthiness (Mollick, 2014). Developing a dedicated crowdfunding platform for PDR projects requires a comprehensive understanding of crowdfunding models and the determinants of campaign success. However, existing research lacks analysis of the critical success factors necessary to adapt crowdfunding as an alternative financing mechanism for PDR. Unlike real estate or housing projects, no dedicated crowdfunding models for PDR have been identified in the literature. Addressing this gap necessitates a thorough evaluation of traditional crowdfunding limitations and the development of a hybrid model tailored to the specific challenges of PDR fundraising. Furthermore, existing literature does not provide practical recommendations or structured guidelines for establishing customised crowdfunding mechanisms in this context. As objectives, the study reviews the types of financing mechanisms in PDR and reviews the crowdfunding concepts, types and processes.

This study comprises a detailed research methodology, followed by a comprehensive literature review that examines different financial mechanisms and then explores the applicability of crowdfunding as an alternative source of funds for PDR projects. Subsequently, the literature findings are discussed with the aid of a proposed conceptual

model for financing PDR projects. Finally, the key conclusions of the study and recommendations for further research directions and practical application are presented.

2. METHODOLOGY

A literature review explores the historical development of the subject matter and studies the key themes by broadening the significance of the study (Saunders et al., 2023). Further, Green et al. (2023) elaborate that a narrative literature review provides a discussion on theory and context, aiming to provoke thought and stimulate controversy. Thus, to achieve the research aim, a narrative literature review was undertaken to explore existing studies on the various financing mechanisms employed in post-disaster reconstruction (PDR) projects, with particular attention to the concepts, types, and processes of crowdfunding. Accordingly, a background study was conducted to understand funding challenges associated with PDR projects and to identify the potential in crowdfunding. Afterwards, a comprehensive literature review was conducted to investigate the types of financing mechanisms employed in PDR projects, examine challenges associated with existing financing mechanisms and explore the potential of crowdfunding to address these challenges.

The existing knowledge obtained through secondary sources such as journal articles, conference papers, books and reports were used for this study. To compile a comprehensive literature synthesis, various keywords were searched with the aid of search engines, including “Google Scholar”, “Emerald Insight”, “Scopus”, and “Science Direct”. In addition, reports and research papers published by professional bodies such as the Cambridge Centre for Alternative Finance (CCAF), European Crowdfunding Network (ECN), World Bank and Crowdfunding Professional Association (CfPA) were reviewed and incorporated into the literature analysis. The selection of keywords was primarily based on the themes associated with the study. Thus, keywords such as “post disaster reconstruction”, “PDR”, “financing method”, “funding methods”, “financial architecture”, “crowdfunding”, “crowdfunding models and topologies”, “investment models in crowdfunding” and “non-investment models in crowdfunding” were selected considering their significance and relevance for the study. However, articles specifically related to the targeted topic were identified after carefully reading the abstract to check for relevance.

The study employed a content-based analysis to analyse the collected literature. This method is commonly used in qualitative research for identifying themes and patterns methodically within textual data (Kongaracki et al., 2002). In this study,content-based analysis was helpful to identify types of financing mechanisms and to analyse the crowdfunding concepts and processes. Subsequently, the study presents a conceptual framework by analysing the operational procedure of the crowdfunding mechanism for PDR projects. A conceptual framework acts as an important research element to assist further investigations in the subject areas (Martín et al., 2019).

3. FINDINGS

3.1 FINANCING ARRANGEMENTS FOR POST-DISASTER RECONSTRUCTION

Suarez and Linnerooth-Bayer (2011) define reconstruction finance as the allocation of funds for the rebuilding and advancement of the constructed environment. According to Ryu and Kim (2018), potential sources may include loans, grants, donations, investments

from partner agencies, and programmatic below-market loans. Current discussions among policymakers and practitioners highlight the difficulty in precisely distinguishing between funding and financing sources, especially when determining whether infrastructure is funded or financed (Strickland, 2016). Hence, project financing serves as an umbrella term encompassing both funding and financing mechanisms in PDR projects. Accordingly, Feather (2021) uses the term 'Financial Architecture for Reconstruction' to describe the holistic mechanism for securing financial resources for PDR, integrating both financing and funding.

Despite its importance, disaster management research lacks a structured understanding of reconstruction finance. Most academic studies emphasise governmental subsidies and risk transfer tools, while practitioner reports often focus on fund disbursement rather than acquisition, overlooking the high costs of rebuilding (Usta et al., 2019). This has resulted in limited insight into how PDR is financed. Although various case studies have attempted to classify financial approaches in different countries, there remains a need for a comprehensive framework in this field (Feather, 2021).

Researchers have developed several classifications to understand the financing architecture for Post-Disaster Reconstruction (PDR). Accordingly, Feather (2021) identifies two main categories: "Ex Ante" and "Ex Post," where the former refers to financial mechanisms established before a disaster occurs, while the latter involves mobilising resources after a disaster through channels like donor aid, government relief, and emergency loans. Accordingly, Table 1 illustrates the different financial mechanisms used to manage risk at different phases of PDR projects.

Table 1: Financing mechanisms for risk management of post-disaster reconstructions
Adapted from: (Feather, 2019; Hammett & Mixter, 2017)

Risk	Ex Ante	Ex Post
Risk Transfer	**Capital Market Instruments**	**Credit**
	Indemnity Insurance	Government Bank Loans
	Parametric insurance	Bank and Non-Bank Lending
	Reinsurance	**Co-Finance**
	Catastrophic bonds	Intergovernmental transfers
	Derivatives	Public-private partnerships
Risk-Retention	**Public finance for disaster budget**	**Government Recovery Program**
	Taxation revenues	Discretionary Aid
	Non-taxation proceeds	**Organisational Resources**
	Lines of contingent capital (Credit)	Household assets, including savings and remittances
		Business revenue
		Civil society grants
		In-kind contributions

Different financing mechanisms are used to manage risk in the form of transfer and retention across various phases of PDR projects. In the ex-ante phase, risk is transferred through capital market instruments, while public funds and contingent credit lines are allocated for risk retention. In the ex-post phase, risk transfer is facilitated through credit

and co-financing mechanisms, whereas government recovery programs and organisational or community resources are used to retain risk.

3.2 SOURCES OF TYPICAL FINANCIAL ARCHITECTURE FOR PDR PROJECTS

3.2.1 Major Capital Providers and Sources of Reconstruction Finance

The various types of financial architecture for reconstruction are built on key funding sources that form the foundation for post-disaster financing. Feather (2021) identifies four primary mechanisms commonly used by property owners: insurance, grants, loans, and capital assets. Insurance functions as a risk transfer tool, offering compensation for property damage and including instruments like government subsidies and catastrophe bonds as proactive financial strategies (Feather, 2019). Grants, provided by governmental and non-governmental organisations, play a key role in funding infrastructure repairs and housing reconstruction (Daly et al., 2020). Loans issued by state bodies or financial institutions are often used to finance rebuilding efforts. Lastly, capital assets and personal or organisational financial resources can also be mobilised by property owners to fund reconstruction. Collectively, these mechanisms form the foundation of post-disaster recovery and are often used in combination to address diverse reconstruction needs.

3.2.2 Challenges with the Capital Providers and Sources

The drawbacks associated with traditional sources of funding for PDR projects are extensively discussed in academic literature. Overall, many authors, including Feather (2021), Ptashchenko and Chechelashvili (2018), discuss the difficulties in achieving funding sources through typical methods for projects with the motive of social well-being. The major reason here is the reluctance of stakeholders to invest in non-profitable social facilities. Furthermore, the governments may also not prioritise the financing of social projects, leading to a gap in funding for the construction.

Table 2: Challenges associated with capital-providing sources

Capital providers and sources	Challenges	References
Insurance	Inadequate coverage, delayed payouts, and complex damage assessments.	(Cummins & Weiss, 2009),
	Government subsidies and catastrophe bonds may lack scalability and effectiveness in large-scale disaster contexts.	(Cebotari & Youssef, 2020)
Grants	The amount of grants is often insufficient for comprehensive reconstruction.	(Banomyong, 2001),
	Grants are affected by bureaucratic processes, uncertain availability and potential misallocation.	(Daly et al., 2020)
	Overreliance on grants may hinder timely and efficient reconstruction efforts.	
Loans	Loans pose challenges such as high interest rates, repayment burdens, and eligibility constraints, limiting access for some property owners.	(Sharma et al., 2018).
	Inadequate loan funding remains a barrier to reconstruction	

Capital providers and sources	Challenges	References
	Slow and bureaucratic application processes can delay fund disbursement, increase costs, and affect project timelines.	
Capital assets	Not readily available or sufficient for all property owners. Upfront fees in traditional financing models.	(Awodele et al., 2022).

In summary, the drawbacks associated with the major sources underscore the importance of considering an alternative effective mechanism. The involvement of multiple sources can be addressed as a problem since financial arrangements for reconstruction can be complex with multiple funding sources, all with their accounting requirements and allocation timeframes (McCawley, 2008).

3.3 CROWDFUNDING AS AN ALTERNATIVE SOURCE OF FUNDS FOR PDR PROJECTS

Crowdfunding can be considered a multifaceted solution for PDR financing, which provides not only financial support but also fosters community engagement. Crowdfunding is a way to collect money from a large group of people, where each person gives a small amount. Instead of getting big amounts from a small group of investors (Belleflamme et al., 2014). Usually, crowdfunding gathers contributions from many backers through the Internet (Short et al. 2017), often without traditional financial intermediaries (Mollick, 2014). This concept originates from applying crowdsourcing principles to fundraising, creating new channels for community-backed financing in various project areas such as business, culture, humanitarian efforts, social causes, politics, environment, and technology (Schwienbacher & Larralde, 2012). Initially, consisting of sporadic independent efforts, crowdfunding has evolved into numerous dedicated platforms that mediate between fundraisers and contributors within a trusted framework. According to data from various platforms, global alternative finance volumes, covering all crowdfunding types, reached USD 371 billion in 2017, growing by 42% from 2016 (Ziegler et al. 2019).

3.3.1 Crowdfunding as a Capital Source for Construction Projects

Crowdfunding is increasingly recognised as an effective financing tool across various industries, including construction (Hoque, 2024). In the real estate sector, crowdfunding helps bridge the funding gap left by traditional banks, as illustrated by Slesarev (2022), who explored how Finnish real estate developers leverage crowdfunding to finance development projects. Similarly, in Nigeria, crowdfunding offers solutions to the limitations of traditional financing, such as restricted fund access, lengthy processes, and high upfront fees, by enabling more inclusive and efficient funding (Awodele et al., 2022). Their research outlines a model where project developers launch campaigns to attract small equity or rewards-based investment and use the funds for construction, particularly beneficial for smaller projects. However, the model carries inherent risks, such as potential fraud and limited investor protection.

3.3.2 Current Status of Crowdfunding in PDR

Crowdfunding has demonstrated effectiveness in supporting immediate relief efforts (Behl and Dutta, 2019). However, research on its application in PDR projects remains limited, with less emphasis placed on long-term reconstruction activities. Ptashchenko and Chechelashvili (2018) advocate for the utilisation of crowdfunding as a means to finance social infrastructure, proposing that crowdfunding platforms can attract investment from socially engaged individuals. They argue that crowdfunding offers a viable solution to bridge financing gaps in the development of innovative ideas and social projects. Within this context, PDR projects can be viewed as a form of social empowerment, providing a meaningful opportunity to explore the potential of crowdfunding in supporting sustainable recovery and reconstruction efforts.

A key consideration in crowdfunding is selecting the most suitable model to achieve specific objectives, as success largely depends on the mechanism employed. Therefore, it is crucial to conceptualise the prominent models currently employed to construct an effective and specific mechanism for funding PDR projects through crowdfunding. Accordingly, reviewing the components and typologies of existing crowdfunding models is crucial.

3.3.3 Main Stakeholders and the Typical Process of Crowdfunding

The essence of crowdfunding revolves around a mutually beneficial dynamic involving three primary stakeholders: the fundraiser, the backer, and the platform. The fundraiser initiates funding campaigns, gaining not only capital but also market exposure, customer engagement, and product feedback (Ryu & Kim, 2018). As another major stakeholder, backers support projects financially and benefit from influencing innovations, improving personal consumption opportunities, and fostering community ties (Shneor & Munim, 2019). Platforms act as intermediaries, connecting fundraisers and backers through online systems, and generate income through success fees and service charges (Belleflamme et al., 2015). Each successful campaign boosts the reputation of the platform and expands its user base (Thies et al., 2018).

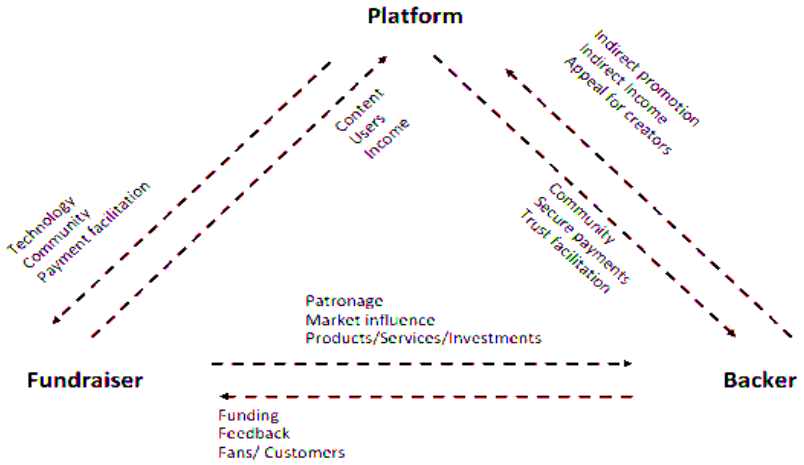

Figure 1: The win-win dynamics of crowdfunding
Source: (Shneor et al., 2020)

At the core of crowdfunding practice lies an expectation for a "win-win" game, where all parties enjoy various benefits from their involvement in the process, as highlighted in

Figure 1 (Shneor et al., 2020). In addition to the main stakeholders, public authorities play a significant role in influencing the crowdfunding industry's development and the interactions between its participants. Regulations, primarily focused on consumer and investor protection, establish the framework for different crowdfunding models. Furthermore, authorities aim to facilitate greater public contributions to civic, cultural, educational, and environmental initiatives, aligning with government policies.

3.3.4 Common Crowdfunding Models and Typologies

The literature categorises crowdfunding models and types according to varying value propositions, practice patterns, funder motivations, associated risks, and regulatory requirements of crowdfunding platforms (Shneor et al., 2020). Belleflamme et al. (2015) propose a basic distinction between 'investment models' and 'non-investment models,' focusing on the nature of compensation promised to funders. Non-investment models involve reward and donation crowdfunding, while investment models encompass lending and equity models, including royalty variations like profit or income sharing.

The CCAF provides a comprehensive categorisation of crowdfunding models in its annual industry reports (Ziegler et al., 2018; Zhang et al., 2018), clearly illustrating the relationships among various crowdfunding types. A simplified version of this categorisation is presented in Figure 02.

Investment based Models

Investment-based crowdfunding models include debt-based, equity-based, and emerging models like invoice trading. Debt-based models, such as peer-to-peer (P2P) and balance sheet lending, connect borrowers with investors or provide loans directly from the platform’s funds. A distinct form, pro-social lending, incorporates social impact goals, with microfinance focusing on small loans to the poor (Short et al., 2017). Equity-based models, including equity crowdfunding, enable investments in unlisted shares of SMEs, expanding into areas like real estate crowdfunding and community shares, where social return often outweighs financial gain (Zhang et al. 2017). Invoice trading allows SMEs to sell invoices at a discount for quick liquidity, aiding short-term cash flow (Dorfleitner et al., 2017).

Non-investment-based Models

Finally, the reward and donation crowdfunding models are arguably the models most commonly recognised by the public. These models typically involve individuals or businesses providing funding to projects without expecting monetary returns. In reward models, funders often receive pre-sales of products or services within a specified timeframe. In donation models, there are no tangible rewards, and funders derive satisfaction from contributing to something they deem important. An interesting variant is patronage, featuring subscription-like payments (rather than a one-time donation) to support ongoing occupations or careers, particularly relevant for artists (Swords, 2017), despite being relatively marginal in the overall crowdfunding sphere so far.

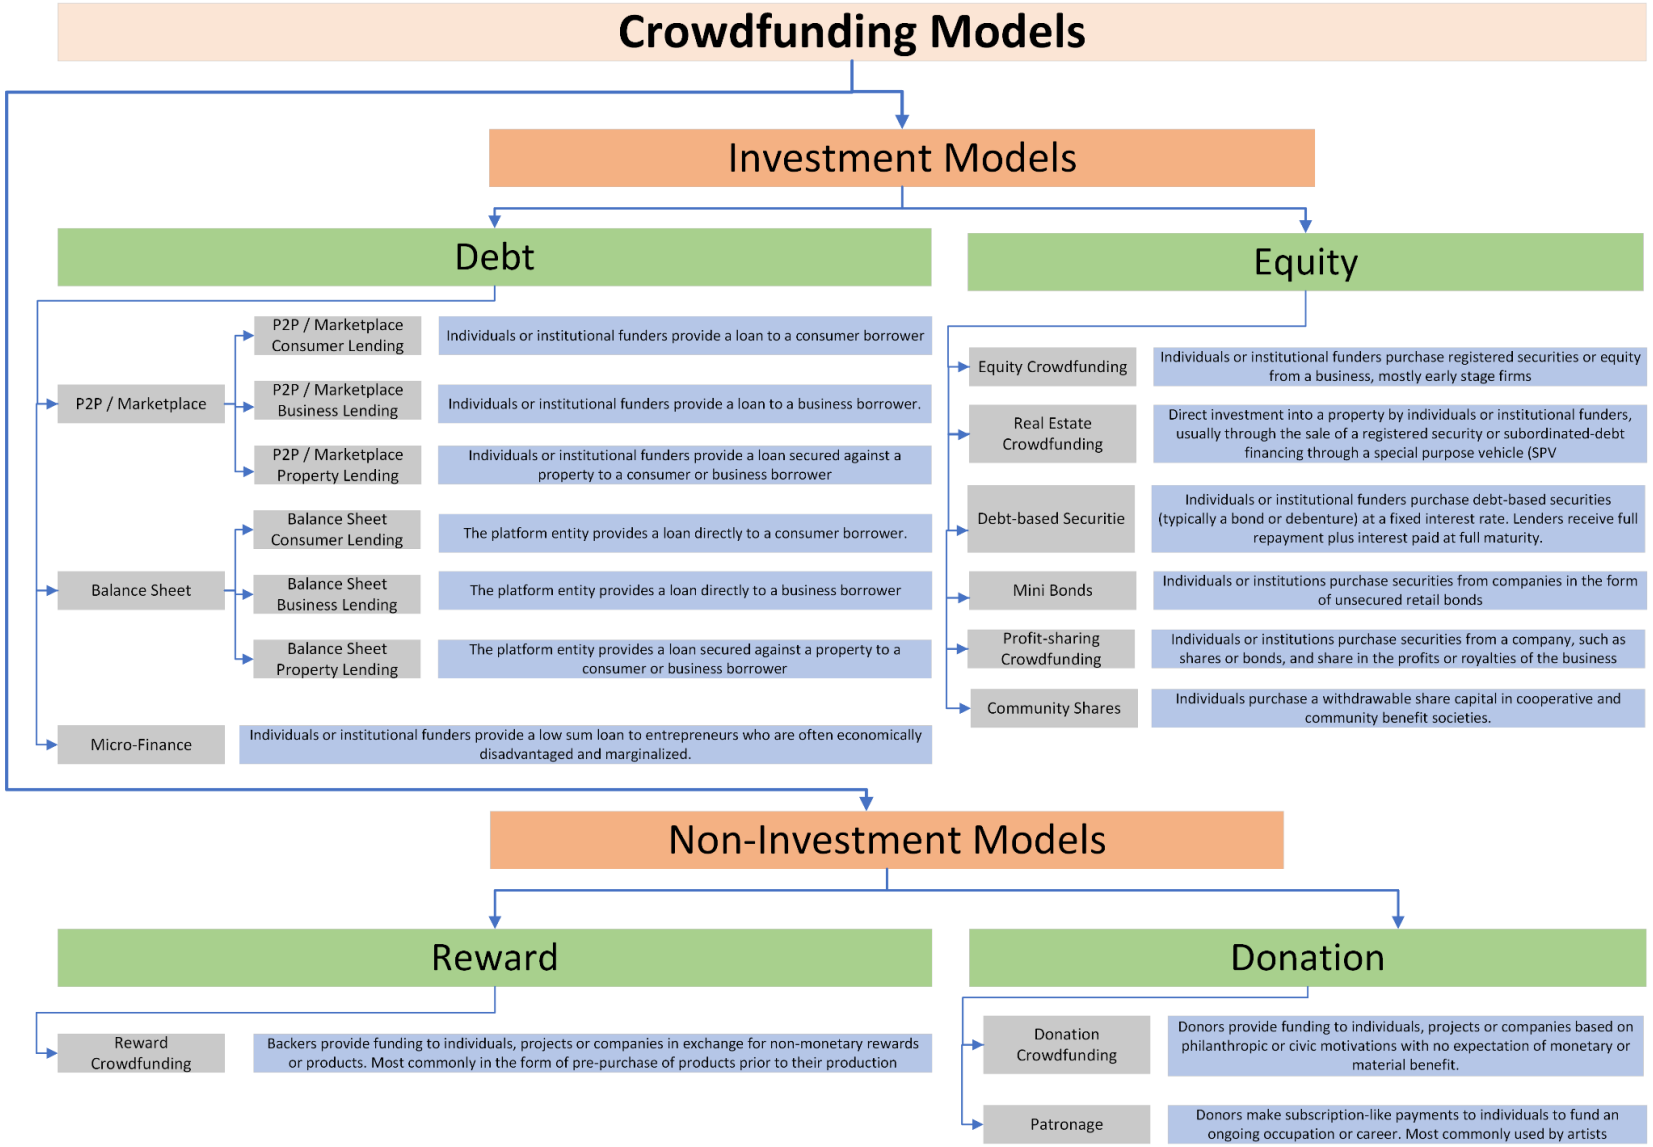

Figure 2: Summary of crowdfunding types/models
Adapted from: (Ziegler et al., 2018; Zhang et al., 2018)

4. DISCUSSION

The growing frequency of natural disasters and conflicts has significantly increased the demand for PRD, essential for restoring normalcy for affected populations. However, a key challenge in implementing these projects lies in securing adequate financing, as PDR projects often lack a standardised financing structure (Feather, 2021). Instead, various financing architectures are employed depending on the context, comparable to architectural designs where similar components are arranged differently. These architectures are built from core revenue streams such as insurance, grants, loans, and capital assets (Feather, 2021). Each of these sources has limitations, affecting the efficiency and success of PDR efforts. As a result, crowdfunding is emerging as a promising alternative, particularly suited for philanthropic causes like disaster recovery. While four primary crowdfunding models exist, the CCAF highlights the potential of developing hybrid models tailored to specific funding needs.

In contrast to traditional capital sources such as insurance, government subsidies, grants, loans, and capital assets, which often suffer from limitations such as inadequate coverage, bureaucratic delays, high interest rates, and limited accessibility (Cummins & Weiss, 2009; Banomyong, 2001; Awodele et al., 2022), crowdfunding offers a more flexible and inclusive financing alternative. Investment-based models, including debt and equity crowdfunding, enable direct engagement between funders and recipients, often with quicker disbursement and broader eligibility (Short et al., 2017). Non-investment-based models, such as donation and reward crowdfunding, foster community-driven support without repayment burdens, providing accessible funding especially in socially motivated contexts (Swords, 2017). Furthermore, crowdfunding platforms can rapidly mobilise dispersed capital, making them particularly suitable for post-disaster recovery or niche funding needs where traditional mechanisms fall short (Ziegler et al., 2018; Zhang et al., 2018).

This paper contributes to the field of PDR by reviewing alternative fundraising mechanisms and identifying the challenges associated with traditional sources such as insurance, grants, loans, and capital assets. It identified crowdfunding as an effective alternative to address persistent financing gaps in PDR projects, particularly due to its potential to mobilise resources efficiently, inclusively, and in support of philanthropic or community-driven initiatives. The study further explores the applicability of various crowdfunding models and the roles of key stakeholders in enhancing funding strategies for PDR. For future advancement, research should focus on empirically validating the proposed model, identifying critical success factors for its practical implementation, and addressing relevant regulatory considerations.

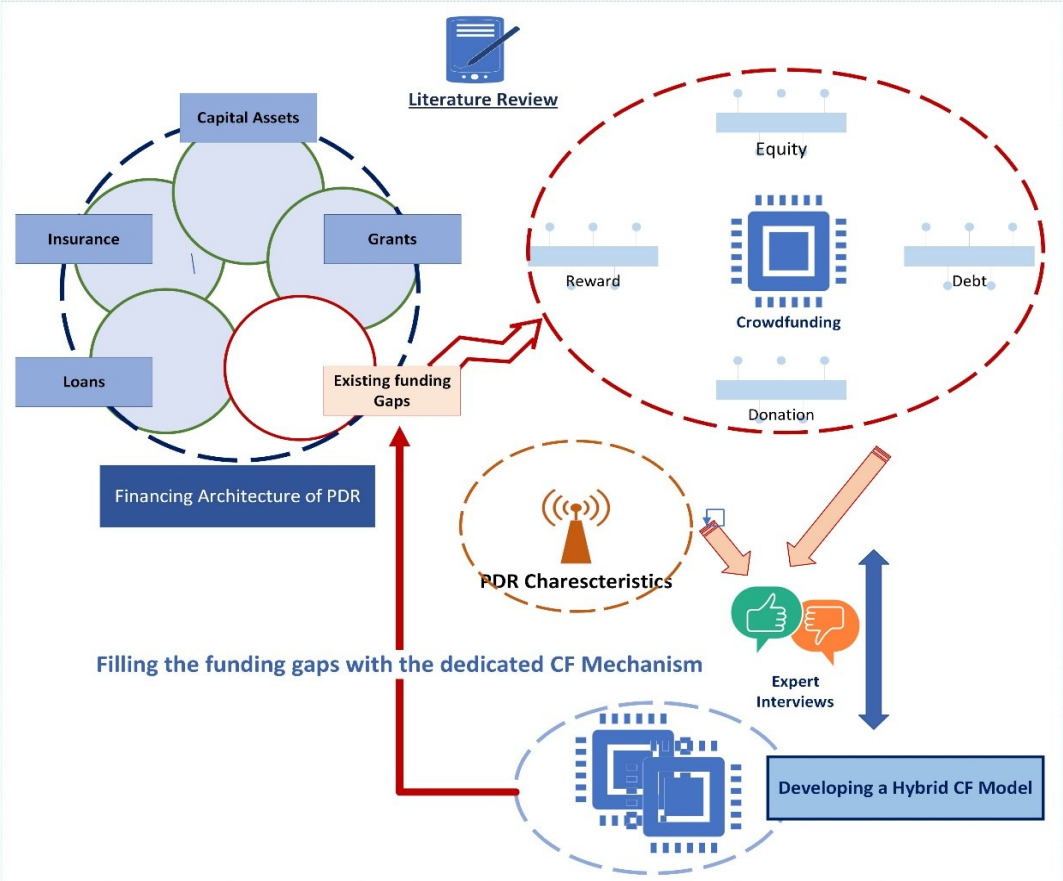

Figure 3: Conceptual framework

5. CONCLUSION AND RECOMMENDATIONS

In conclusion, the research focuses on the financial issues related to the PDR projects that significantly impact throughout the entire project lifecycle. Among the financial challenges, insufficient funding is a major issue due to huge funding requirements and limited funding availability because of the inherent nature of PDR projects. Therefore, the typical financing methods of PDR projects and the issues with sources of funds are analysed and evaluated through the literature findings. Crowdfunding, as an emerging funding tool, has proven to be a viable alternative source of capital for various types of projects, particularly in the construction sector, such as real estate and condominium developments. Its unique features, such as decentralised funding, community engagement, and flexibility, make it especially suitable for these project types. Similarly, PDR projects, which represent a distinct category of construction with urgent and socially driven objectives, can also benefit from the implementation of crowdfunding to attract necessary funds and bridge financing gaps often left by traditional mechanisms.

The study offers substantial contributions across multiple dimensions. Socially, it proposes an inclusive funding model that empowers affected communities and enhances participatory engagement. Economically, it introduces an alternative mechanism for the efficient mobilisation of capital for PDR projects. Academically, it addresses a notable gap in the literature by situating crowdfunding within the broader discourse of disaster recovery finance. Furthermore, research provides a conceptual guideline for industry practitioners to adopt crowdfunding as an alternative financing mechanism for attracting

funds. Moreover, the study aligns with and supports the advancement of several SDGs, specifically SDG 11 Sustainable Cities and Communities, SDG 9 Industry, Innovation and Infrastructure and SDG 17 Partnerships for the Goals.

Nonetheless, the research adopts a narrative literature review approach, which, while offering valuable thematic insights and conceptual clarity, inherently limits empirical generalizability. Therefore, future research should focus on evaluating the viability and effectiveness of the proposed crowdfunding framework for funding PDR projects. Moreover, as further research should explore the potential of integrating blockchain and Building Information Modelling (BIM) for developing crowdfunding platforms.

6. ACKNOWLEDGEMENT

The authors greatly acknowledge the technical support given by AADWV Udayashantha, Staff Technical Officer, Department of Building Economics, University of Moratuwa.

DECENT WORK ENFORCEMENT GAPS: ADAPTING GLOBAL LESSONS INTO SRI LANKAN CONSTRUCTION INDUSTRY

Sathyami Dissanayake[1], D.N.L.S. Uduwage[2] and R.A.B.U.N. Perera[3]

ABSTRACT

The construction industry, while vital for economic development, faces significant challenges in achieving Sustainable Development Goal 8 (SDG 8), particularly Target 8.5, which emphasizes decent work, fair wages, and productive employment. This study investigates the barriers to SDG 8.5 implementation in Sri Lanka's construction sector through a mixed-methods approach, combining bibliometric analysis and qualitative literature review. Findings reveal critical gaps in awareness, with research predominantly focused on productivity metrics rather than worker welfare, as evidenced by weak co-occurrence of SDG 8.5-related keywords. Key barriers include gender disparities, market-driven exploitation, informal sector reliance, and stakeholder policy gaps, which hinder progress toward decent work. The study identifies three strategic interventions—promoting gender equality, strengthening labour rights, and formalizing informal work—as essential for aligning Sri Lanka's construction industry with global standards. These insights provide actionable recommendations for policymakers and industry leaders to foster a more equitable and sustainable workforce, ensuring the sector's contribution to inclusive economic growth by 2030.

Keywords: *Construction Industry; Decent Work; Sri Lanka; SDG 8; Sustainable Employment.*

1. INTRODUCTION

The construction industry is inherently labour-intensive, relying heavily on human resources to execute planning, design, building, and maintenance activities (Fei et al., 2021). Unlike many other sectors where automation and technology dominate, construction remains deeply dependent on manual labour for its operations (Buntara et al., 2018). Buntara et al. (2018) has mentioned that labour intensiveness underscores the critical importance of safeguarding worker rights and ensuring decent working conditions. Without adequate protections, the industry faces severe repercussions, including high turnover rates, reduced productivity, and increased occupational hazards (Fadhilah et al., 2023). Labour rights are not merely ethical imperatives but also economic necessities, as the stability and growth of the construction sector hinge on the well-being

and motivation of its workforce (Fei et al., 2021). Failure to address these issues can lead to systemic inefficiencies, project delays, and diminished quality, ultimately undermining the industry's contribution to national development (Buntara et al., 2018).

Ensuring decent work is a globally recognized priority, particularly through Sustainable Development Goal 8.5 (SDG 8.5) under the United Nations (UN) agenda, which promotes safe, fair, and equitable employment. Despite the global recognition, many countries still face considerable challenges in fully realizing these objectives, especially in labour-intensive sectors such as construction (Chigbu & Nekhwevha, 2023). Even in developed nations, enforcement of decent work standards often requires continuous policy updates, workforce education, and strong institutional support (Islam, 2020). As a committed UN member state, Sri Lanka has committed to advancing the Sustainable Development Goals (SDGs), particularly Sustainable Development Goal 8 (SDG 8), which promotes sustained, inclusive, and sustainable economic growth, full and productive employment, and decent work for all. Target 8.5 of this goal explicitly calls for equal pay, safe working environments, and fair employment opportunities, principles that are especially relevant to the construction sector (Islam, 2020). Globally, many UN member states, such as the UK, Australia, and Germany, have made significant strides in aligning their construction industries with SDG 8.5 by enforcing stringent labour laws, promoting gender equality, and investing in worker training and safety programs (Chaha & Rani, 2024). Falk (2007) stated that these efforts have not only improved working conditions but also enhanced productivity and social equity within the industry. However, Sri Lanka lags in these advancements, with persistent challenges hindering progress. The absence of suitable strategies leaving the sector ill-equipped to meet international standards (Morton et al., 2017).

As a member of the United Nations, Sri Lanka is committed to achieving the SDG 8.5 by the year 2030. In line with this national commitment, it is essential for the Sri Lankan construction industry to adapt practices of SDG 8.5. However, prior to implementing such standards within the local construction sector, it is necessary to examine the existing body of literature to understand current research trends and the extent of awareness related to decent work in the Sri Lankan context. Identifying these patterns enables the recognition of knowledge gaps and informs the adaptation of international best practices. Furthermore, by analysing global strategies and challenges, context-specific barriers can be understood, thereby facilitating the development of appropriate interventions to support the integration of SDG 8.5 into the Sri Lankan construction industry. To achieve this aim, following objectives were formulated.

- To assess the current awareness and implementation of SDG 8.5 in Sri Lankan construction sector.
- To identify the key barriers impeding progress and propose actionable strategies to integrate decent work principles into the industry.

Through this research, policymakers, industry leaders, and stakeholders can gain insights to foster a more equitable, productive, and sustainable construction workforce in Sri Lanka. This study initially reviews existing academic literature to assess research trends related to SDG 8.5 in Sri Lanka, utilizing secondary sources such as peer-reviewed publications. A bibliometric analysis was then conducted to map these trends, followed by a manual content analysis to identify key barriers to achieving decent work in the construction industry.

2. LITERATURE REVIEW

The SDGs, adopted by all UN member states in 2015, represent a universal call to action to end poverty, protect the planet, and ensure prosperity for all by 2030 (Zulu et al., 2023). Comprising 17 interconnected goals, the SDGs address global challenges through a holistic framework that balances economic, social, and environmental dimensions (Morton et al., 2017). Among these, SDG 8 (Decent Work and Economic Growth) stands out as a critical driver of sustainable development, aiming to promote "sustained, inclusive, and sustainable economic growth, full and productive employment, and decent work for all" (Ogunmakinde et al., 2022). This goal recognizes that economic progress must be equitable, creating opportunities for meaningful employment while safeguarding workers' rights and well-being.

Table 1 narrowing the focus, Target 8.5 of SDG 8 specifically emphasizes achieving "full and productive employment and decent work for all women and men, including for young people and persons with disabilities, and equal pay for work of equal value" (Paksi et al., 2024).

Table 1: Targets and indicators of SDG 8.5

Target	Description	Indicators
8.5	By 2030, achieve full and productive employment and decent work for all women and men, including for young people and persons with disabilities, and equal pay for work of equal value	8.5.1 - Average hourly earnings of female and male employees, by occupation, age and persons with disabilities. 8.5.2 - Unemployment rate, by sex, age and persons with disabilities.

Figure 1 shows the four pillars of decent work, and this target highlights the importance of fair wages, job security, and safe working conditions particularly relevant to labour-intensive industries (Morton et al., 2017). According to the researcher, the construction sector, as one of the largest global employers, plays a pivotal role in advancing SDG 8.5.

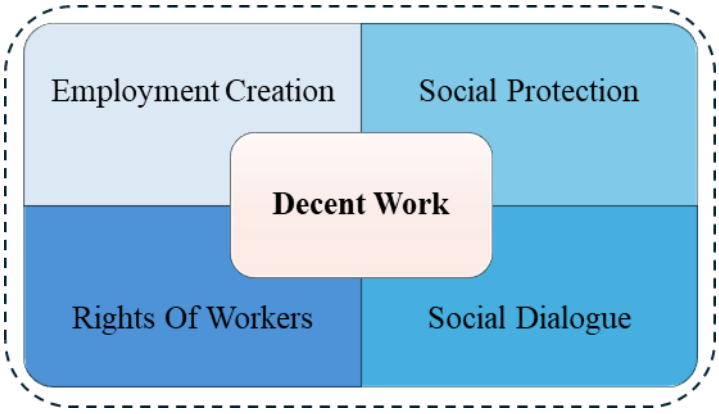

Figure 1: Four pillars of decent work

The construction industry in Sri Lanka is of key importance to the national economic development as it has a significant contribution to Gross Domestic Production and employment generation (Gnanothayan & Kauškale, 2022). However, though the sector is of key importance, it lags in adopting the principles of SDG 8.5, that is, to ensure full and productive employment and decent work for all by 2030 (Colombage et al., 2023). Informal employment, absence of social protection, weak occupational health and safety

standards, and limited occupational skill development are typical of labour conditions in the industry (Ranasinghe & Kumarasinghe, 2019). These affect especially the marginalized group like migrant workers, daily wage earners, women in construction.

Comparative studies point out that unlike Sri Lanka, developed countries like Australia and Germany have been much more successful in establishing decent work frameworks in their construction industries (Zulu et al., 2023). Strong labour regulation, stakeholder collaboration and worker protection, fair wages and job security have been enforced in these countries (Zulu et al., 2023). This gap is in the absence of similar structures and policies in Sri Lanka as a developing country. As Dissanayake et al. (2021) point out, this gap highlights the necessity of context-specific strategies that can adapt and localize successfully international practice to the socio-economic, and cultural setting in Sri Lanka. To meet global sustainability goals as well as to have a fairer, safer and more productive workforce in the Sri Lankan construction sector, these enforcement gaps need to be addressed.

3. RESEARCH METHODOLOGY

This study employs a mixed-methods approach to comprehensively address its dual research objectives. The combination of quantitative bibliometric analysis and qualitative literature review was deliberately chosen to provide both macro-level awareness patterns and micro-level contextual insights (Bornmann, 2022). While pure quantitative methods might overlook nuanced challenges, and purely qualitative approaches could lack measurable trends, this blended methodology offers complementary strengths that enhance the validity and applicability of findings.

The first objective is focusing on scrutinizing the current awareness and implementation of SDG 8.5 in Sri Lankan construction sector as Figure 2 illustration show. Thus, bibliometric analysis was used to achieve this objective, where quantitatively evaluate the academic literature to identify the trends of publication data such as, authorship, key words, citations, co-citation, affiliation and journals. Subsequently, study extract the critical barriers from literature using manual content analysis which gives qualitative information. The review covers publications from 2015 to 2024, aligning with the UN's adoption of the SDGs in 2015. As per Figure 2, the Scopus database was chosen for its comprehensive coverage of peer-reviewed construction literature, with the search string which mentioned below, specifically designed to capture SDG 8.5 related concepts while filtering for Sri Lankan context (Cantu-Ortiz, 2018). The subsequent co-occurrence and cluster analysis of 80 papers enables to quantify research gaps and knowledge concentrations that indicate national awareness levels.

Search string: TITLE-ABS-KEY (SDG8 OR decent OR work OR productive OR employ AND construction AND Sri AND Lanka) AND PUBYEAR > 2014 AND PUBYEAR < 2025 AND (LIMIT-TO (SUBJAREA , "ENGI") OR LIMIT-TO (SUBJAREA , "ECON”) OR LIMIT-TO (SUBJAREA , "SOCI”)) AND (LIMIT-TO (DOCTYPE , "ar") OR LIMIT-TO (DOCTYPE , "cp"))

The search query was developed based on following criteria; the key words should be SDG 8, decent work, productive employment, construction, and Sri Lanka. The articles should be published withing 2014-2025 and it should be a journal or conference written in English. VOSviewer was used to conduct the bibliometric analysis based on gathered data. This approach was preferred over traditional surveys or interviews because it: (1)

objectively measures existing scholarly attention through publication patterns, (2) reveals invisible networks between research themes, and (3) provides visualizable data trends across time.

Following three types of bibliometric analysing techniques were employed to achieve the first objective.

1. Co-Authorship Analysis

This is a method to study the collaborative relationships among researchers, institutions or countries, which are based on shared authorship in academic publications. This method demonstrates how knowledge is produced and shared across geographical and institutional boundaries. One of the most important advantages of co-authorship analysis is identifying influential researchers, research groups, and potential collaborators in each domain. It offers a quantifiable and objective view of collaborative patterns.

2. Co-occurrence Analysis

Academic articles are analysed to determine how often certain keywords occur together in them. It is a technique through which one acquires the subtle theme, topic and trend of an area of research. The major advantage of the keyword co-occurrence analysis is that it provides a visually and systematically mapped conceptual structure of the literature. It helps in identifying underexplored area and gives a better proposition for future research direction.

3. Co-Citation Analysis

This is the analysis of how often two documents are cited together by other publications, therefore suggesting that they are linked or similar in content. Co-citation analysis can be used to find tides in how knowledge about a concept is acquired over time, unlike expert opinion or qualitative assessment. It provides a historical view for the evolution of research topics, which is hard to achieve through interviews or manual literature reviews.

Figure 3 represent the research process of second objective, and it adopts a qualitative systematic review methodology to examine global barriers and strategies. It prioritized over meta-analysis or case study approaches because it: (1) allows for thematic synthesis of diverse international experiences, (2) captures policy and implementation nuances lost in statistical analyses, and (3) facilitates identification of transferable best practices. The content analysis process involved iterative coding of literature from multiple databases to ensure thematic saturation. This method was selected over automated text mining as it enables deeper interpretation of contextual factors and more accurate categorization of complex strategies. The qualitative findings are systematically organized to highlight both universal principles and culturally specific adaptations relevant to Sri Lanka's construction sector.

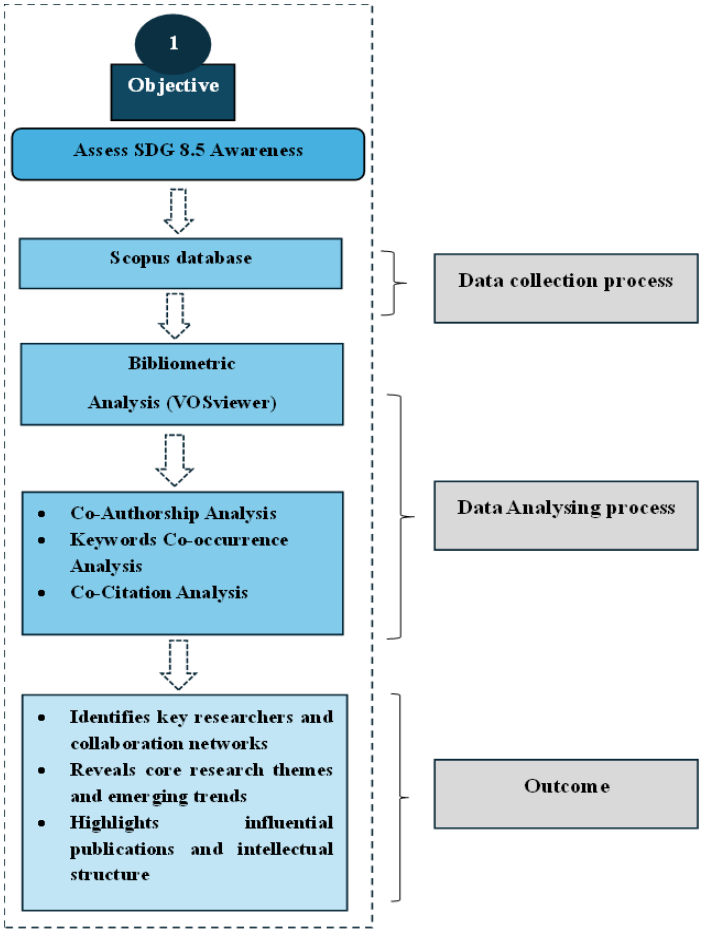

Figure 2: Methodology of objective 01

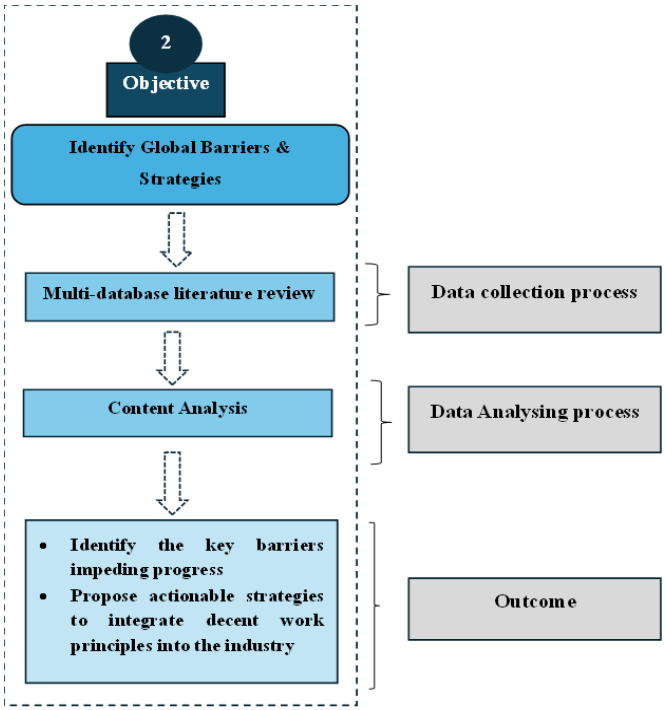

Figure 3: Methodology of objective 02

4. DATA ANALYSIS AND DISCUSSION

This section analysis the gathered data and discuss the results.

4.1 AWARENESS OF SRI LANKAN CONSTRUCTION INDUSTRY ABOUT SDG 8.5

This section examines the level of awareness among stakeholders in the Sri Lankan construction industry regarding SDG 8.5, which focuses on achieving full and productive employment and decent work for all by 2030. The analysis draws on data collected to assess how familiar industry professionals are with the goals, targets, and relevance of SDG 8.5 to their daily operations and strategic planning.

4.1.1 Co-authorship Mapping

Figure 4 shows the Co-authorship analysis of Sri Lankan construction research, and it reveals limited but strategic collaborations around SDG 8.5 themes, with key authors like Dissanayake and Manoharan (link strength:19) forming strong research clusters, while isolated high-producers like Perera (7 papers) and low-citation works (e.g., Waidyasekara:1 citation) indicate fragmented knowledge dissemination. The concentration of decent work research within small academic circles, combined with weak industry-policy linkages (evident in Dodanwala's 117 citations but minimal collaborations), highlights critical gaps in translating SDG 8.5 awareness into practical implementation. Strengthening interdisciplinary networks between technical experts (Ranadewa), policymakers (Senaratne), and institutional researchers could bridge this divide, transforming academic insights into actionable strategies for improving labour conditions, gender equity, and formal employment in Sri Lanka's construction sector.

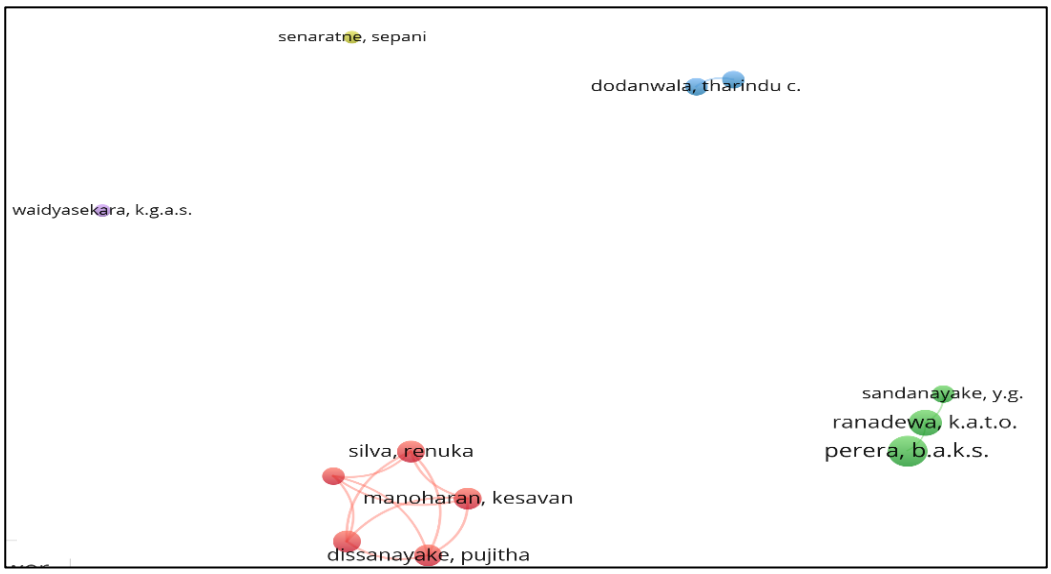

Figure 4: Bibliographic analysis co-authorship

4.1.2 Co-occurrence Analysis

The bibliographic analysis of co-occurrence of keywords of Sri Lankan construction research reveals a predominant focus on project management, cost reduction, and sustainable development, evidenced by large, interconnected nodes, while themes central to SDG 8.5 such as job stress, well-being, and role ambiguity appear as small, isolated

nodes, indicating severe neglect of decent work principles. As per the Figure 5, each node represents a keyword. The size of the nodes reflects the frequency of keyword appearance, and links between nodes indicate how often those keywords appear together in publications. Different colours represent thematic clusters, helping to identify major research areas and interrelated topics.

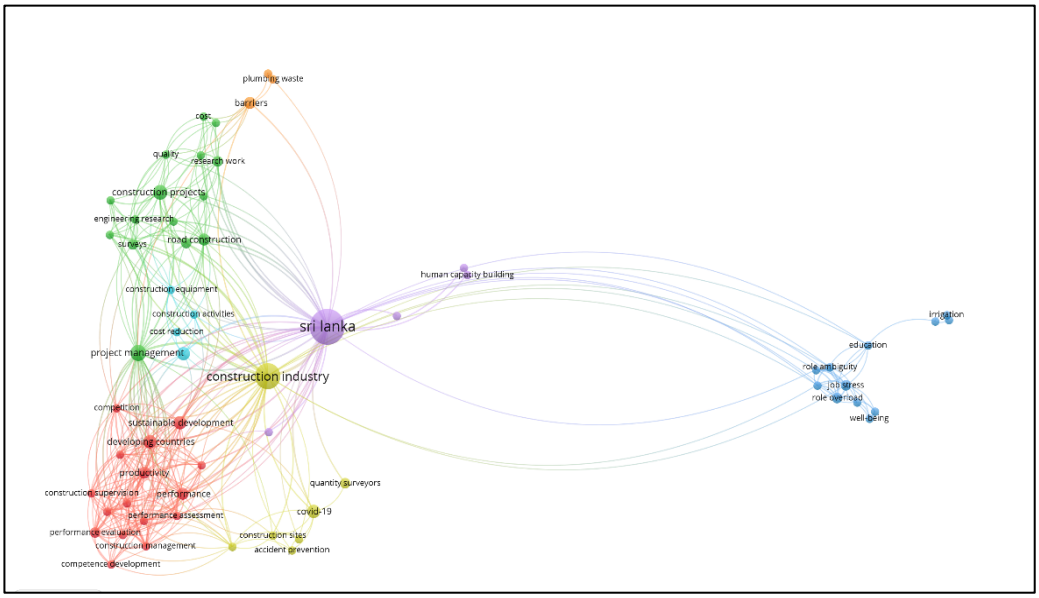

Figure 5: Bibliographic analysis of co-occurrence of keywords

This disparity highlights the industry's entrenched prioritization of productivity metrics over worker welfare, with critical gaps in research on employment conditions, psychological safety, and equitable opportunities. The weak co-occurrence of SDG 8.5-related keywords underscores an urgent need for rebalancing academic and policy attention toward human-centric studies, which could transform workplace practices and align Sri Lanka's construction sector with global sustainability targets through evidence-based interventions targeting worker empowerment and inclusive growth.

4.1.3 Co-Citation Analysis

The co-citation analysis reveals influential research relationships shaping SDG 8.5 discourse in Sri Lanka's construction sector, with *Dissanayake P.* (366 link strength) and *Deegahawature D.* (363) forming the dominant intellectual cluster, indicating their foundational role in decent work research. While local scholars demonstrate strong interconnectivity, the limited co-citation of international experts like *Lingard H.* (23) and *Ballard G.* (83) suggests weak integration of global decent work frameworks into local studies. This insular citation pattern reflects a disconnect *between Sri Lankan research and international SDG 8.5 advancements*, particularly in occupational health and gender equity. The high link strength among local authors (*Silva R.*, *Manoharan K.*) confirms concentrated expertise, but the sparse citations of labour sociology pioneers (*Koskela L.*, *Thornhill A.*) highlight a critical gap in applying cross-disciplinary insights to improve worker welfare. Strengthening co-citation networks with global decent work literature could accelerate policy-relevant research to address Sri Lanka's construction labour challenge.

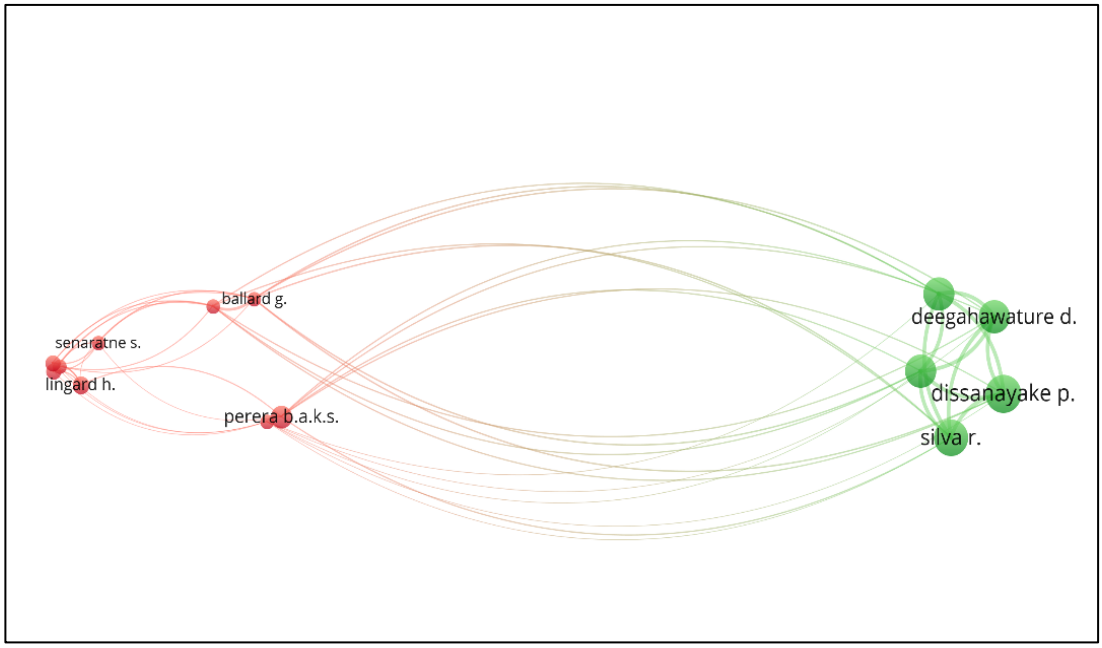

Figure 6: Bibliographic analysis of co-citation

Results of the bibliometric analysis of co-authorship, co-occurrence of keywords and co-citation mapping corroborate the fact that the construction research in Sri Lanka is specialized and yet limited in its engagement with SDG 8.5. Dissanayake-Manoharan is one of the small research clusters that demonstrate strong local influence, but the larger academic environment is characterized by fragmented collaboration, weak interdisciplinarity, and minimal international linkage. Analysis of keyword shows that cost and project performance dominate while themes of decent work like well-being and job security are sidelined. In addition, citation patterns indicate that there exists a lack of the use of literature on the global decent work to aid the sector to adopt inclusive labour strategies. These findings therefore directly meet Objective 01 by documenting the current level of awareness and research engagement regarding SDG 8.5 in Sri Lanka's construction industry and identify key areas that need academic and practical attention to promote productive and decent work in the Sri Lankan construction industry.

4.2 BARRIERS IN ACHIEVING DECENT WORK IN CONSTRUCTION INDUSTRY

The content analysis of global literature reveals six persistent barriers hindering SDG 8.5 implementation in the construction industry, categorized into four thematic areas: gender disparities, market economy pressures, informal sector reliance, and stakeholder gaps. Table 2 shows the summary of analysis of barriers. Gender inequality emerges as a cross-cutting challenge, with studies highlighting systemic discrimination, wage gaps, and limited leadership opportunities for women and persons with disabilities (Anojan & Siriwardana, 2021; Pourmazaherian M. & Musonda, 2022; Silva, 2018). Maqbool et al. (2023) states, market-driven exploitation manifests through cost-cutting practices that depress wages and weaken labour rights enforcement, while Anaman & Amponsah (2007) mentioned informal employment exacerbates vulnerabilities through absent legal protections and social security. Critically, stakeholder failures particularly inadequate policies and awareness perpetuate these issues (Anaman & Amponsah 2007; Maqbool et al., 2023). The Table 2 demonstrates how these barriers intersect globally, with

developing nations facing acute informalization and developed economies struggling with equitable growth, underscoring the need for context-specific strategies to achieve decent work.

Table 2: Barriers in achieving decent work in construction industry

	Barrier	A	B	C	D	E	F
Gender Disparities	Systemic discrimination	✓			✓		
	Wage gaps		✓			✓	
	Limited leadership opportunities for women	✓	✓	✓			
	Limits job opportunities (Women and Persons with Disabilities)	✓					
	Inadequate training opportunities		✓		✓		✓
Market Economy Pressures	Cost-driven exploitation	✓					
	Low wages						
	Lack of labour rights enforcement		✓		✓		✓
Informal Sector Reliance	Lack of legal protections	✓					
	Lack of social security				✓		✓
	Lack of safe conditions for informal workers		✓				
Stakeholders	Lack of awareness and understanding		✓			✓	
	Lack of effective policies that promote decent work			✓			✓

A- (Pourmazaherian M. & Musonda, 2022), B- (Anojan & Siriwardana, 2021), C- (Silva, 2018). D- (Bruno & Oliveira, 2024), E- (Anaman & Amponsah, 2007), F- (Maqbool et al., 2023)

4.3 STRATEGIES TO OVERCOME FROM BARRIERS IN ACHIEVING DECENT WORK IN CONSTRUCTION

Table 3 indicates the analysis which identifies three key strategic approaches to advance SDG 8.5 in the construction sector: promoting gender equality, strengthening labour rights, and formalizing informal work. As per the Islam (2020), gender-focused strategies emphasize equal pay laws, leadership representation, and targeted training programs to address systemic disparities. Labor rights reinforcement highlights stricter law enforcement, union support, and worker complaint mechanisms to combat exploitation (Chaha & Rani, 2024; Islam, 2020). For informal sector challenges, solutions centre on accessible registration, social benefits, and skills development to transition workers into formal employment (Chaha & Rani, 2024; Chigbu & Nekhwevha, 2023). These strategies directly counter the identified barriers with gender initiatives tackling discrimination, labour policies addressing market pressures, and formalization measures reducing

informal sector vulnerabilities demonstrating a targeted, multi-pronged framework for achieving decent work globally.

Table 3: Strategies to overcome from barriers

	Strategy	A	B	C	D	E	F
Promoting Gender Equality	Enforcing equal pay laws	✓					
	Improving fair representation of women in leadership and technical roles		✓		✓		✓
	Providing mentorship and vocational training			✓			
	Conducting Pursuing programs that encourage women and PWD	✓			✓		
Strengthening Labor Rights	Implement stricter enforcement of labour laws	✓	✓				
	Supporting unions	✓					✓
	Ensuring complaint mechanisms for workers.						
	Ensure legal protections for workers	✓		✓			
Formalizing Informal Work	Establish accessible registration processes			✓			✓
	Provide financial and social benefits to encourage formalization		✓				
	Expanding vocational training and skills development opportunities	✓			✓		✓

A-(Islam, 2020), B-(Chaha & Rani, 2024), C-(Chigbu & Nekhwevha, 2023), D-(Zulu et al., 2023), E-(Khalique et al., 2021), F-(Fei et al., 2021)

The synthesis of barriers and strategies based on global literature offer a holistic view of the challenges and their solutions associated with the achievement of SDG 8.5 in the construction industry. The analysis identifies systemic gender disparities, market pressures, informal sector dependence and stakeholder failures as key barriers which strategic pathways of promoting gender equality, strengthening labour rights and formalising informal work can help overcome. The findings are consistent with Objective 02 since they provide a comprehensive appraisal of current global approaches and identify feasible tactics that can be adopted to Sri Lanka's construction context. The analysis makes a significant contribution to formulating a context sensitive roadmap for decent and productive work in the industry by linking the root causes with appropriate interventions.

5. CONCLUSIONS AND RECOMMENDATIONS

This research examined the enforcement gaps in the achievement of SDG 8.5, which aims to achieve full and productive employment and decent work for all in the construction industry of Sri Lanka. The study is important because although the construction sector contributes a great deal to the national GDP and employment, it lags in adopting fair labour practices, equal opportunity policies and worker welfare standards. The study

utilized a mixed methods approach, whereby bibliometric analysis was used to assess national awareness, identify key barriers, propose strategies that were globally informed and pertinent to the Sri Lankan context from a qualitative systematic review.

The findings suggest that the awareness of SDG 8.5 is not very high, and that research is mainly concentrated on productivity and project management, rather than employment conditions and workers' rights. Co-occurrence and co-authorship mapping of the keywords showed fragmented scientific attempts, poor participation of expert stakeholder and minimal global best practice integration. Gender disparity, market driven exploitation, reliance on informal sector and policy gaps were identified as key barriers. To that effect, three strategic recommendations were provided: the promotion of gender equality; the strengthening of labour rights; and formalising informal work, all aimed at making progress towards decent work.

Nevertheless, this study has a few limitations. This study used only Scopus indexed literatures yet, there are literature which are not indexed in the Scopus but have appeared in other databases. Although rich in context, the qualitative analysis relied purely on secondary data and did not include direct stakeholder interview or field-level feedback. Empirical surveys or interviews with industry practitioners, labour unions and policymakers, should be conducted to validate and refine the proposed strategies in the future research.

DEFINING GREEN BUILDING CRITERIA FOR BUILDING INFORMATION MODELING-BASED RATING SYSTEMS

Mustika Sari[1], Mohammed Ali Berawi[2], Rahmadi Surya[3], Gunawan Saroji[4], Nunik Madyaningarum[5], Siti Rahma Utami[6] and Rafly Muzady[7]

ABSTRACT

As sustainability becomes increasingly central to architectural and construction practices, robust frameworks are needed to evaluate and guide the implementation of green building (GB) standards. Integrating Building Information Modelling (BIM) with GB criteria presents a promising approach to advancing sustainable construction. BIM provides a comprehensive digital representation of a building's physical and functional characteristics and has the potential to streamline sustainability assessments by aligning traditional GB standards with data-driven design and evaluation processes. In Indonesia, the adoption of GB principles remains limited due to the complexity of building design and evaluation. This paper explores GB criteria tailored for BIM-based rating systems based on the Regulation of the Minister of Public Works and Public Housing No. 21 of 2021. Data were collected through a literature study and analyzed using expert judgment. The findings classify the criteria into two categories: (1) those that can be directly integrated with BIM and (2) those that require manual assessment. The study identifies 18 criteria suitable for BIM integration and 11 that depend on manual processes. These results illustrate the opportunities and constraints of using BIM to support GB assessments.

Keywords: *Building Information Modelling; Green Building; Rating System.*

1. INTRODUCTION

The growing urgency of climate change and rapid urbanization has increased the pressure on the building and construction sector to adopt sustainable practices. This sector is

responsible for nearly 40% of energy-related carbon emissions worldwide. As a response, many governments now promote the use of green building (GB) standards to reduce environmental impacts. In Southeast Asia, GB initiatives have become more prominent part of national strategies for sustainable development. GBs not only provide environmental benefits but also reduce life-cycle costs (Zuo & Zhao, 2014). GBs help conserve natural resources, enhance occupant well-being, and improve building performance (Sari et al., 2022). Various GB technologies have been developed to suit local construction contexts, although most research still focuses on isolated components rather than integrated solutions.

To achieve long-term sustainability in building projects, stakeholders need a comprehensive understanding of how to design, construct, operate, and manage buildings responsibly. As a result, sustainability assessment has become an essential approach in the development process (Reed et al., 2017). Green Building Rating Systems (GBRSs) support this goal by providing structured tools that evaluate building performance against defined sustainability criteria. These systems help ensure that sustainable design requirements are met and that environmental objectives are achieved (Romano & Riediger, 2020). In Indonesia, however, the use of GBRS remains limited by challenges in adapting frameworks to national regulations and local conditions. Addressing these constraints is necessary to accelerate the adoption of sustainable construction practices.

While GBRS provide a strong foundation for sustainability evaluation, their effectiveness can be improved through digital tools such as Building Information Modelling (BIM) (Seghier et al., 2018). BIM provides a centralized platform for visualizing and managing building data. It supports sustainability assessment by enabling automation, improving accuracy, and simplifying the certification process (Doan et al., 2023). BIM is also capable of supporting detailed modelling and simulation at every building's life cycle.

Over the past two decades, BIM has transformed the architecture, engineering, and construction (AEC) industry, and has been widely used for communication and coordination in design, construction, and facility management (Wong & Kuan, 2014). The main benefits of BIM include better decision-making, faster access to information, improved performance analysis, and more efficient GB certification (Ilhan & Yaman, 2016). Studies show that BIM-based GB evaluations can enhance building performance by 31.5%, reduce energy use, and improve indoor comfort (Guo et al., 2021). BIM has already supported green certification frameworks in several countries. In New Zealand, BIM is used for 75% of the Green Star Certification Tool (GhaffarianHoseini et al., 2017). In Australia, it contributes to 66% of credits under the Green Star system (Gandhi & Jupp, 2014). It has also been used in Canada (Jalaei & Jrade, 2014), Portugal (Carvalho et al., 2021), and Malaysia (Solla et al., 2022) to support national GB certifications.

Although these developments show clear progress, most studies still focus on limited aspects of integration between BIM and GBRS. Researchers have primarily explored energy efficiency, material selection, or partial system automation. For example, the BIM-based GBRS developed by Romano and Riediger (2020) emphasizes energy-related features. The framework developed by Rahman et al. (2021) includes only Energy and Atmosphere (EA) and Material Resources (MR) in alignment with LEED. Additional studies have examined the use of BIM for automatic assessments (Motamedi et al., 2017), green certification support (Seyis et al., 2021), and verification of sustainability goals

(Alwan et al., 2015). However, few studies have offered a complete view of how national GB criteria can be fully embedded within BIM-based systems.

This research focuses on Indonesia's Regulation of the Minister of Public Works and Public Housing No. 21 of 2021, which aims to identify which of these criteria are relevant to BIM-based evaluation and to classify them based on their compatibility with BIM tools through expert validation. The goal is to support the development of a more structured and technology-enabled approach to GB evaluation in Indonesia. The findings are expected to provide practical guidance for BIM practitioners, researchers, and policymakers in strengthening GB practices within the Indonesian context.

2. GREEN BUILDING RATING SYSTEM CATEGORIES

GB refers to a structured approach that minimizes the negative environmental impact of construction activities while preserving natural resources across a building's life cycle (Sari et al., 2022). Indonesia is one of the developing countries that attempts to massively adopt GB concept. Indonesia's GB assessment framework, outlined in the Regulation of the Minister of Public Works and Public Housing, organizes criteria into six main categories: Appropriate Site Development (ASD), Energy Efficiency and Conservation (EEC), Water Conservation (WAC), Use of Material Resources and Cycle (MRC), Indoor Health and Comfort (IHC), and Building Environment Management (BEM). These categories align with global GBRSs such as LEED and BREEAM (Surya et al., 2024).

ASD focuses on minimizing environmental disruption through site planning, with indicators include building orientation, accessibility, land remediation, green spaces, and infrastructure alignment. LEED addresses these under Location and Transportation (LT) and Sustainable Sites (SS) (Ismaeel & Elsayed, 2022), while BREEAM emphasize more on pollution control and soil protection during construction (Telichenko et al., 2019).

EEC addresses the optimization of a building's energy performance across its systems. EEC emphasizes efficient energy use across building systems, including envelopes, HVAC, lighting, and power distribution. LEED assesses these elements through the Energy and Atmosphere (EA) category (Pushkar, 2021), while BREEAM highlights performance tracking, metering, and low-carbon sourcing (Pritchard & Kelly, 2017).

WAC supports water efficiency through reliable sourcing, low-consumption fixtures, and reuse systems. LEED's Water Efficiency (WE) category includes indoor and outdoor water strategies (Poon, 2021). BREEAM assesses water use from a broader operational perspective that includes user behaviour (Zegarra, 2021).

MRC encourages reduced material impact through responsible selection, waste prevention, and life cycle thinking. LEED promotes certified materials and transparency in sourcing and embodied carbon (Zegarra, 2021). BREEAM expands this by rewarding efficient design, reuse, and supply chain oversight (Shukla et al., 2015).

IHC addresses occupant health and comfort through air quality, thermal performance, and refrigerant safety. LEED captures these under Indoor Environmental Quality (EQ) and emphasizes measurable indicators such as ventilation and lighting (Lee & Kim, 2008). BREEAM includes additional factors such as ergonomics and access to views, with both systems emphasize the importance of using non-toxic and well-commissioned systems (United States Green Building Council, 2021).

BEM encompasses waste and wastewater management. Indicators include the 3R principles, monitoring systems, and on-site treatment. LEED promotes construction waste diversion and landfill reduction (Chi et al., 2020), while BREEAM stresses end-use waste and water recovery infrastructure (Luangcharoenrat & Intrachooto, 2018).

3. METHODS

This study was structured around two research objectives and conducted in two stages, each involving different data collection and analysis approaches.

3.1 IDENTIFICATION OF GREEN BUILDING CRITERIA

To address the first objective, data were sourced from Indonesia's Regulation of the Minister of Public Works and Public Housing No. 21 of 2021 on Green Building Performance Assessment and from previous studies related to GB certification and BIM applications. Data collection was conducted through document analysis and a literature study. Relevant criteria were extracted and grouped under categories such as site management, energy efficiency, water conservation, and others. These criteria were examined using content analysis to determine their structure and assess whether they matched the characteristics of information stored and processed within BIM models.

3.2 CLASSIFICATION OF BIM-COMPATIBLE CRITERIA

The second objective was addressed through expert validation. Five experts participated in the study, including a BIM consultant, two BIM practitioners, one government regulator, and one academic researcher. All were selected based on their professional experience in BIM implementation and GB evaluation. Data were collected through structured interviews using a validation form that listed all criteria identified in the first stage. Experts assessed whether each criterion could be integrated into BIM or required manual input. Closed-ended questions were used to maintain consistency and clarity throughout the process (Creswell, 2018; Woodhead & Berawi, 2008).

4. RESULTS AND DISCUSSION

4.1 IDENTIFICATION OF GREEN BUILDING CRITERIA

This subsection addresses the first research objective: identifying GB assessment criteria from Indonesia's Regulation of the Minister of Public Works and Public Housing No. 21 of 2021 on Green Building Performance Assessment that align with BIM functionalities. The analysis was conducted by extracting criteria from the regulation and organizing them into six main categories (Kamath et al., 2019; Wardhana et al., 2023).

Each criterion was examined through document analysis and supported by a literature review to determine its alignment with data types and modelling outputs typically found in BIM environments. Prior studies such as Akhanova et al. (2021), Jalaei & Jrade (2014), and Alwan et al. (2015) served as key references in associating regulatory requirements with BIM functionalities, including parametric modelling, spatial coordination, energy simulation, and material tracking.

The result of this process is summarized in Table 1, which lists 29 GB criteria drawn from the regulation along with relevant references that indicate prior studies that support the technical feasibility of assessing each criterion using BIM. These sources were used to

validate the relevance of each criterion to BIM functionalities such as modelling, simulation, or automated data extraction. These criteria form the foundation for the classification of BIM compatibility.

Table 1: Green building assessment criteria identified from national regulation

Category		Criteria	References
1. ASD	1.1	Building Orientation	Alwan et al. (2015)
	1.2	Site management including accessibility or circulation	Jalaei & Jrade (2014), Seyis et al. (2021), Akhanova et al. (2021)
	1.3	Management of land contaminated with hazardous & toxic waste (B3)	Akhanova et al. (2021)
	1.4	Private green open space plan	Akhanova et al. (2021), Seyis et al. (2021)
	1.5	Provision of walkways	Akhanova et al. (2021)
	1.6	Basement tread management	
	1.7	Parking Lot Provision	Jalaei & Jrade (2014)
	1.8	Outdoor lighting system

	6.3	Implementation of Waste Generation Recording System	
	6.4	Provision of Wastewater Treatment Facilities Before Discharge to City Sewers	Jalaei & Jrade (2014)

4.2 CLASSIFICATION OF CRITERIA BASED ON BIM COMPATIBILITY

This subsection presents the results of the second research objective, which aims to classify the identified GB criteria based on their compatibility with BIM. The classification was carried out through expert validation using a structured form that listed all 29 criteria extracted from Indonesia's Regulation of the Minister of Public Works and Public Housing No. 21 of 2021 on Green Building Performance Assessment. Five experts that participated in the validation process each had over ten years of professional experience in GB certification or BIM implementation.

The experts assessed whether each criterion could be evaluated using BIM authoring tools or whether manual assessment was necessary. The instrument included binary response options (BIM-based / Manual) and provided space for additional comments. Responses were analyzed to identify which criteria aligned with quantifiable or spatial parameters available in BIM environments, like Autodesk Revit or Green Building Studio (GBS).

The results confirmed that 18 criteria could be evaluated using BIM. These criteria correspond to parameters that can be modelled, simulated, or extracted from BIM platforms. For example, building orientation and lighting systems can be assessed through spatial modelling and daylight simulation, while energy systems such as HVAC and electrical loads are compatible with BIM-integrated performance tools.

CO_2 and CO control can be addressed through space scheduling and pollutant tracking features in Autodesk Revit, which allow simulation of indoor air exchange and monitoring of emissions based on room occupancy and mechanical system configurations (Akhanova et al., 2021). Lighting systems are assessable through daylight simulation and artificial lighting analysis, where BIM tools simulate natural light penetration and optimize lighting layout in accordance with building codes and sustainability standards Jalaei & Jrade (2014). Ventilation and HVAC systems can be modelled using tools such as GBS, which supports airflow simulation, thermal zoning, and mechanical load distribution for performance evaluation.

Energy efficiency calculations are also supported by BIM through dashboards that simulate building energy use and estimate contributions from renewable sources. For water use efficiency, BIM enables water consumption modelling and plumbing fixture representation to estimate total demand and potential savings. Lastly, environmentally friendly materials can be managed in BIM through tagging, quantity take-off, and data exports that support verification of material sources and compliance with eco-labelling or low-impact material requirements (Alwan et al., 2015; Seyis et al., 2021).

The remaining 11 criteria require manual evaluation due to the absence of direct digital representation in BIM or because they involve qualitative elements. These include criteria such as construction above public infrastructure, implementation of waste management systems, and smoking bans. Evaluation of such elements often depends on regulatory interpretation, post-occupancy monitoring, or documentation that must be verified externally. This classification is detailed in Table 3, which categorizes each criterion by its compatibility with BIM-based assessment.

Table 2: Green Building Criteria that can be evaluated using BIM

No.	Category	BIM-integrated	Manual Entry
1	ASD	1.1 Building Orientation	1.3 Management of land contaminated with hazardous & toxic waste (B3)
		1.2 Site management including accessibility or circulation	1.5 Provision of walkways
		1.4 Private green open space plan	1.7 Parking Lot Provision
		1.6 Basement tread management	1.9 Construction of Building above and/or under Land, Water, and/or Public Infrastructure/Supplies
		1.8 Outdoor lighting system	
2	EEC	2.1 Building envelope	
		2.2 Ventilation system	
		2.3 Air conditioning system	
		2.4 Lighting system	
		2.6 Energy efficiency calculation	
		2.7 Electrical system	
3	WAC	3.1 Water Source	
		3.2 Water usage	
		3.3 Use of water efficiency sanitary equipment	
4	IHC	4.2 Carbon dioxide (CO2) and carbon monoxide (CO) control	4.1 Smoking Ban
		4.3 Refrigerant Usage Control	
5	MRC	5.1 Controlling the Use of Hazardous Materials	
		5.2 Use of Eco – Labelling Certified Materials	
6	BEM		6.1 Application of the 3R Principle (Reduce, Reuse, Recycle)
			6.2 Implementation of Waste Management System
			6.3 Implementation of Waste Generation Recording System
			6.4 Provision of Wastewater Treatment Facilities Before Discharge to City Sewers

The results of this study confirm that BIM can support a substantial portion of Indonesia's GB assessment framework, particularly in categories that rely on quantifiable and spatial data. EEC, WAC, and IHC show high levels of integration with BIM tools and offer strong potential for automation in energy simulation, water efficiency analysis, and indoor environmental monitoring (See Figure 1). In contrast, ASD and MRC include both BIM-integrated and manual-entry criteria, which reflects the need for hybrid approaches in areas involving site-specific design or material documentation. BEM emerges as the least compatible category since all indicators require manual assessment due to their dependence on post-construction operations, waste handling, or regulatory documentation. These findings suggest that while BIM can digitalize sustainability evaluations in many areas, full automation across all GB criteria remains limited.

Integrating BIM into the certification process provides benefits beyond data assessment. BIM centralizes project information, improves visual clarity for reviewers, and reduces duplication in documentation. This allows certification teams to generate compliant submissions more efficiently using model-based outputs. For criteria that cannot be assessed through BIM, supporting materials such as technical reports, annotated plans, or regulatory checklists should be prepared separately and submitted alongside BIM outputs. A hybrid approach that combines digital automation with manual verification ensures that both quantifiable and qualitative criteria are addressed consistently during certification.

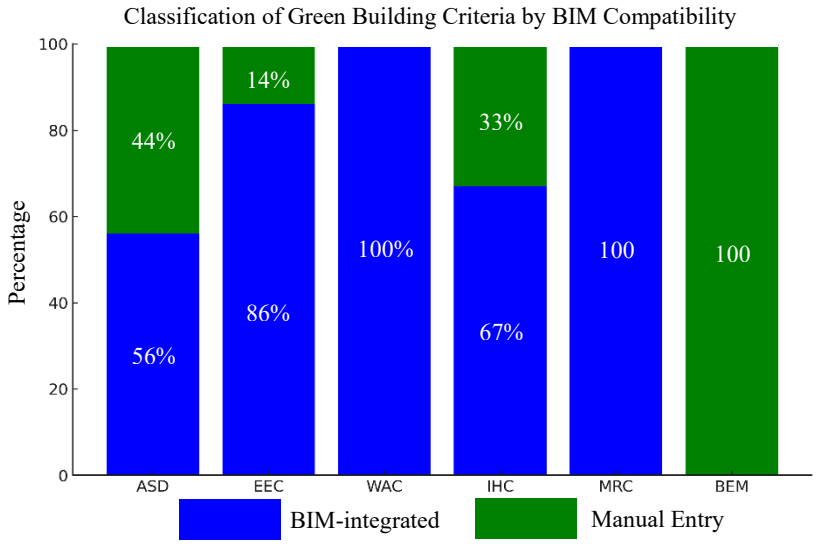

Figure 1: Classification of green building criteria by BIM compatibility

4.3 COMPARISON WITH PREVIOUS STUDIES

The findings of this study are consistent with previous research that confirms BIM's ability to support automated assessments across various GBRSs. Prior studies confirm that core criteria, such as EEC, WAC, IHC, ASD, and MRC, are suitable for integration into BIM-based workflows. Lim et al. (2021) introduced a computational BIM workflow built on Dynamo that enabled automation of assessments for EEC, IHC, ASD, and MRC under Malaysia's GBI. Khoshdelnezamiha et al. (2020) created the AGBIA tool, which combined Revit and Dynamo to address five major evaluation categories: EEC, MRC, WAC, IHC, and ASD. Nguyen et al. (2016) enhanced LEED assessments through a BIM-enabled framework that supported multiple green design metrics. Lai et al. (2023) conducted a comprehensive review that showed BIM frequently supports evaluation of

EEC, WAC, ASD, and MRC criteria, especially when integrated with plug-ins or visual scripting tools like Dynamo. Seghier et al. (2017) demonstrated a more technical application by developing a BIM-based method to evaluate ETTV, aligned with energy requirements in the Green Mark and GreenRE certification systems. These studies affirm the results of this research by highlighting BIM's strength in managing quantifiable and performance-driven indicators through modelling and simulation. At the same time, they also identify limitations in BIM's ability to address qualitative or regulation-specific indicators, such as waste management and construction restrictions, which often require manual input or external review.

Although this study focuses on criteria drawn from Indonesia's Regulation No. 21 of 2021, it is necessary to compare these criteria with the rating systems widely used in practice, such as LEED and GBCI. The categories across these systems are broadly similar, particularly in their inclusion of energy, water, materials, and indoor environmental quality. However, the methods of assessment show important differences. The Indonesian regulation primarily adopts a compliance-based structure, where each criterion must be fulfilled in a binary fashion. The Indonesian framework follows a binary compliance model, while LEED and GBCI apply point-based scoring that recognizes partial achievements. This flexibility supports project customization and encourages continuous improvement through higher-level goals.

Beyond structure, international systems often incorporate elements absent from the national regulation. LEED includes innovation credits, lifecycle assessments, and post-occupancy evaluations. These allow project teams to demonstrate ongoing performance, which is not yet part of the Indonesian system. Enhancing the regulation with adaptive scoring and performance monitoring would improve alignment with global practices and strengthen long-term sustainability outcomes.

5. CONCLUSIONS

This study defines a set of green building (GB) assessment criteria based on their potential for integration with Building Information Modelling (BIM). From a total of 29 regulatory criteria outlined in Indonesia's Ministerial Regulation No. 21 of 2021, 18 were identified as suitable for BIM-based evaluation. These include elements that rely on quantifiable data and spatial modelling, particularly in the categories of energy efficiency, water conservation, and indoor health. The remaining 11 criteria require manual assessment due to their qualitative nature or lack of representation in BIM environments.

The main contribution of this study is the development of a regulatory-specific classification framework that links national GB assessment criteria with BIM functionalities. This study offers a localized and practical approach to integrating BIM into Indonesia's sustainability assessment framework. The results provide actionable insights for policymakers, professionals, and stakeholders seeking to adopt digital methods for green building certification.

There are limitations that should be noted. The scope of this study is confined to Indonesia's Regulation No. 21 of 2021 and does not extend to other certification frameworks. Criteria that involve regulatory interpretation, post-construction documentation, or behavioural outcomes remain beyond the current capacity of BIM-based evaluation. Future research should explore ways to address these gaps by

integrating BIM with post-occupancy monitoring systems and by comparing the alignment of national GB regulations with BIM across different countries.

DETECTION OF MOBILE PHONE USE BY LABOURERS ON CONSTRUCTION SITES USING YOLOV11-S

D.N.L.S. Uduwage[1], S. Sivanraj[2], K.G.A.S. Waidyasekara[3], R.K. Shiwakoti[4] and M. Tripathi[5]

ABSTRACT

Mobile phone distractions among construction labourers pose significant productivity challenges. This study presents a YOLOv11-s-based model to detect and classify construction labourers who use mobile phones during work. The system was trained using a person dataset, a helmet dataset and a mobile phone dataset, obtained from an online database and custom images collected from Sri Lankan construction sites. The proposed system followed a four-stage approach, beginning with person detection, followed by helmet detection and classification. Then, through image preprocessing, the model analysed the helmet colour using histogram analysis and the Hue Saturation Value colour scale to detect labourers with yellow helmets. Subsequently, the performance evaluation metrics, such as precision-recall curve, mAP@0.5 and inference time, indicate that the trained model performs better on the testing data in detecting construction labourers who are using mobile phones during work. Finally, mobile phone detection is carried out. Images from Sri Lankan construction sites were used for deployment validation and to check for model overfitting. The system can be further developed by using motion detection through IoT to detect the continuous use of mobile phones through timeframe analysis. This study contributes to improving workplace productivity through the automated detection of distractions in construction.

Keywords: *Construction; Helmet Detection; Mobile Phone Detection; Productivity; Yolov11,*

1. INTRODUCTION

Construction labour productivity is defined as the amount of work completed per unit of labour input, typically measured in output per labour hour (Assaad et al., 2023). According to Hamza et al. (2022), it is a crucial factor in the construction industry, as it directly influences project efficiency and cost-effectiveness. However, distractions on-site can decrease productivity and lead to delays, inefficiencies, and increased operational costs. Distractions can arise from various sources (Ke et al., 2021), one of which is mobile phone usage on construction sites. Although mobile phones facilitate instant

communication and coordination (Hasan et al., 2019), their unregulated use can become a major source of distraction due to the constant flow of notifications, messages and calls, which can easily become a source of distraction (Merchán et al., 2024).

To mitigate these issues, tighter supervision of labourers' mobile phone usage on construction sites is necessary. According to Hamza et al. (2022), supervision significantly enhances productivity. However, Raoofi et al. (2024) found that traditional supervision methods in construction can be time-consuming and costly. A case study conducted by Kim et al. (2023) in Korea highlighted that digital technologies can significantly enhance the efficiency of construction supervision. Automated systems utilising cameras and computer vision can detect, localise and classify mobile phones. The use of Artificial Intelligence (AI) in construction management can improve efficiency and reduce costs (Ruchit & Olivia, 2024).

One effective way to distinguish construction labourers from other personnel is through helmet colour detection. Studies have shown the feasibility of computer vision models in detecting labourers wearing construction helmets (Cheng, 2024; Hayat & Morgado-Dias, 2022; Li et al., 2023). Merchán et al. (2024) conducted a study to detect the use of mobile phones through an inertial measurement unit for safety monitoring. However, this approach relied on sensors embedded in helmets focusing on detections in indoor scenarios. Therefore, there is still a gap between the detection of mobile phone use in the external environment of the construction site.

This paper introduces a mobile phone detection model that uses the YOLOv11-s architecture to enhance productivity on construction sites. The model achieves this by (1) detecting persons, (2) detecting and classifying safety helmets (3) detecting the colour of helmets to differentiate labourers with yellow helmets, and (4) detecting their use of mobile phones. By integrating computer vision into construction supervision, this approach provides a solution to enhance productivity at construction sites. The paper is structured as follows. First, it provides a comprehensive review of labour productivity and computer vision for enhancing productivity. Next, the research method, including data collection and analysis techniques, is elaborated. This is followed by the findings and conclusions.

2. LITERATURE REVIEW

2.1 SIGNIFICANCE OF LABOUR PRODUCTIVITY ON CONSTRUCTION SITES

Construction productivity plays a vital role in the growth of a nation's economy (Naoum, 2016). Productivity in construction refers to the maximisation of output while optimising input utilisation, ensuring efficiency and cost-effectiveness (Hamza et al., 2022). According to Muqeem et al. (2011), construction labour is the most crucial resource in the industry, directly impacting overall construction productivity. However, low productivity levels remain one of the major challenges faced by the construction sector, leading to delays, increased costs, and inefficiencies. Dixit et al. (2019) further emphasised that low productivity can create inflationary pressure on a nation's economy, affecting overall economic stability.

One of the contributors to reduced labour productivity is mobile phone distractions among labourers (Sattineni & Schmidt, 2015). Labourers who divide their attention between critical tasks and mobile phone use are more likely to exhibit decreased efficiency, leading to lower work output and increased errors (Merchán et al., 2024).

Traditional supervision methods for maintaining productivity rely on manual monitoring, which is often time-consuming and costly (Raoofi et al., 2024). As a result, researchers are increasingly exploring technology-driven solutions to enhance productivity and automate site supervision (Adamu et al., 2024; Bai et al., 2023; Yuan et al., 2023).

2.2 COMPUTER VISION FOR ENHANCING PRODUCTIVITY AT CONSTRUCTION SITES

With the rapid growth of Artificial Intelligence (AI), computer vision has emerged as a significant tool for information perception and automated detection in various applications. In construction safety, helmet detection has been significantly enhanced using computer vision algorithms, enabling real-time monitoring of compliance on construction sites (Cheng, 2024). Numerous studies have utilised Convolutional Neural Networks (CNNs) to detect helmet usage, improving labour productivity and site supervision. Fang et al. (2018), utilised faster regional-based CNN to detect helmet use on construction sites, while Wu et al. (2019) and Han and Zeng (2022) developed deep learning-based systems that detected helmet usage and classified its colour.

CNN-based object detection models are categorised into single-stage and multi-stage detectors (Sumit et al., 2020) . Single-stage detectors, such as You Only Look Once (YOLO), perform object classification and localisation in a single step, making them significantly faster in object detection (Pham et al., 2020). In contrast, multi-stage detectors, such as Faster R-CNN and Mask R-CNN, use a two-step process, which results in higher accuracy but slower processing (Sumit et al., 2020)The primary advantage of single-stage detectors is their real-time capability, making them ideal for applications that require fast object detection. Therefore, YOLO models are an optimal choice for automated construction site supervision, which prioritises speed while maintaining a satisfactory level of accuracy.

The architecture of YOLO consists of three major components: (1) Backbone, (2) Neck, and (3) Head (He et al., 2024). The backbone is responsible for feature extraction within an image, identifying key visual patterns necessary for object detection. The neck enhances multi-scale feature fusion, enabling the model to detect objects of different sizes with improved accuracy. Finally, the head is responsible for final object classification, bounding box regression and refining detection accuracy (Alif, 2024).

2.3 YOLOV11 ARCHITECTURE

Among the YOLO series, YOLOv11 represents the latest iteration, offering significant improvements in real-time object detection (Khanam & Hussain, 2024). It incorporates a range of architectural enhancements designed to improve speed, accuracy, and adaptability. Lin (2024) proposed a YOLOv8-based algorithm designed to enhance helmet detection in complex backgrounds, including instances with small or distant objects. Furthermore, other studies have also used various YOLO models for safety helmet detection on construction sites (Wan et al., 2024; Yang et al., 2024). According to He et al. (2024), YOLOv11 demonstrated the highest accuracy and recall rate compared to previous YOLO versions. A comparison of key performance metrics of the YOLO series is provided in Table 1.

Table 1: Comparison of YOLO series
Source: (He et al. 2024)

Method	mAP/%	Precision/%	Recall/%
YOLOv5	54.4	64.5	62.6
YOLOv8	55.5	71.1	60.9
YOLOv9	43.8	55.2	50.7
YOLOv10	48.0	79.3	56.2
YOLOv11	57.2	66.4	64.8

The YOLOv11 series includes multiple variants designed for different application requirements. These variants, such as YOLOv11-n (nano), YOLOv11-s (small), YOLOv11-m (medium), YOLOv11-I (intermediate), and YOLOv11-x (extreme), offer a balance between accuracy, speed, and computational efficiency (Kishor, 2024). YOLOv11-s is particularly suitable for medium-scale applications, providing a balance between detection speed and accuracy.

2.4 SIGNIFICANCE OF THE STUDY

This study introduces a computer vision system using YOLOv11-s architecture to detect mobile phone use among construction labourers, which is a critical yet underexplored factor in construction productivity. Some studies have focused on helmet detection (Cheng, 2024; Hayat & Morgado-Dias, 2022) and indoor mobile use using sensors (Merchán et al., 2024). However, no studies have integrated person detection, helmet detection and mobile phone detection for alternative manual supervision for enhancing construction productivity. The system aims to offer a scalable, real-time alternative to manual supervision with implications for improving the productivity of labourers at construction sites.

3. METHODOLOGY

3.1 DATASET COLLECTION

Three datasets were used to train the model: (1) for person detection, (2) for "helmet" referred to as "hard hat" detection and (3) for mobile phone detection. These datasets were obtained from an online platform called RoboFlow, which provides a collection of images and associated annotations, specifically designed for training computer vision models. RoboFlow was chosen due to its high-quality and annotated datasets. The dataset consisted of construction images taken from different locations for the model development. Custom images from Sri Lankan construction sites were also incorporated for deployment validation and to identify overfitting. The images were standardised to a resolution of 640×640×3 (RGB scale) to ensure the consistency of the dataset throughout the model training, testing and validation processes.

The person dataset consisted of 5,483 images, with 80% allocated for training, 19% for validation, and 1% for testing. The hard hat dataset contained images of construction labourers with helmets (labelled as "hard hats") and no helmets (labelled as "no hard hats"). The hard hat dataset consisted of a total of 19,745 annotated images, with 70% allocated for training, 20% for validation, and 10% for testing. The mobile phone dataset consisted of 10,768 annotated images, capturing various instances of mobile phone usage by people. The dataset was divided into 82% for training, 14% for validation, and 4% for

testing. These splits ensured that the model had a large enough dataset for learning, testing and validation. For this study, it was assumed that wearing a yellow hard hat is mandatory for construction labourers in Sri Lanka.

3.2 MODEL TRAINING

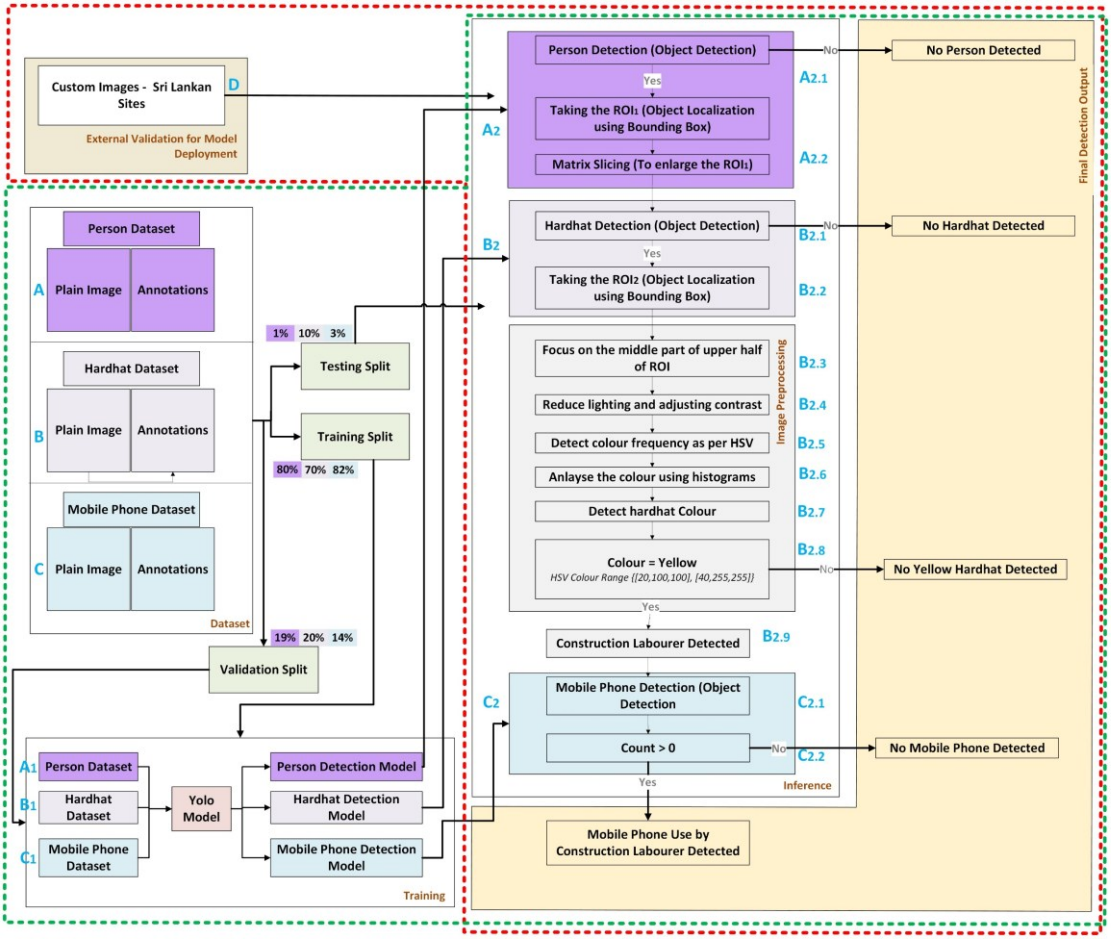

Figure 1: Overall architectural diagram of YOLOv11-s model for detection of mobile phone use by construction labourers

3.2.1 Hyperparameters

Before training, various hyperparameters are utilised to balance the model performance and computational efficiency. These hyperparameters are configuration variables that control the training process by determining the complexity, learning rate, batch size and other variables (Andonie, 2019). According to Alif (2024), key hyperparameters of the YOLOv11 models are learning rate, momentum, weight decay, batch size and the number of epochs. The learning rate of a model indicates how quickly a model learns based on the dataset, whereas momentum accelerates the training process by smoothing out updates of the model. Weight decay is a regularisation technique that prevents the model from overfitting. Batch size represents the number of training datasets processed at once. The number of epochs refers to the number of times the model processed the entire dataset.

In the model, all the hyperparameters, apart from the epochs number were preset with the values in Table 2. In this study, the model was trained for 100 epochs, allowing it to refine the internal parameters based on error calculations.

Table 2: Key parameters for YOLOv11-s training

Hyperparameter	Value
Learning Rate	0.01
Momentum	0.937
Weight decay	0.0005
Batch Size	16 images

3.2.2 Training Process

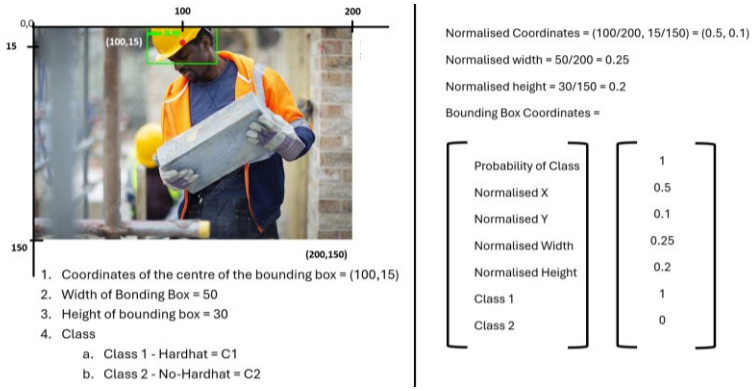

Figure 2: Bounding box coordinates

After splitting each dataset into training, validation, and testing sets, the YOLOv11-s architecture was trained in three phases, as illustrated in Figure 1. The steps have been labelled as "A" for person detection, "B" for hard hat detection, and "C" for mobile phone detection. Additionally, the model development and deployment processes are represented using two types of dotted boxes: the green-coloured dotted box indicates training, internal validation, and testing, while the red-coloured dotted box represents external validation using custom Sri Lankan images. The first phase (A1) involved identifying the region of interest (ROI) by detecting people in the image and applying matrix slicing to separate the ROI area while storing the original coordinates of the ROI within the image. During this stage, the model performed object localisation by generating bounding box coordinates, assigning a confidence score, and classifying detections as person or no-person. The bounding box coordinates were determined as shown in Figure 2. Here, if a person was detected in the image, the model was trained to process only the selected region of interest (ROI) to the next phases. The total training time of the person detection model was 2.416 hours.

Similarly, in the second phase (B1), the model was trained to detect construction hard hats and accurately localise their positions within the image, where detected objects were classified as either hard hat or no-hard hat. The total training time for the hard hat detection model was 6.827 hours. In the third phase (C1), the model was trained using the mobile phone dataset to detect and localise mobile phones. Unlike the person detection model and hard hat detection model, C1 focused solely on detection, where the model was trained to determine whether a mobile phone was present in an image, without further classification. The total training time for the mobile phone detection model was 5.192 hours.

3.3 MODEL VALIDATION (INTERNAL)

During each training epoch, the model underwent an internal validation process to assess its performance and generalisation ability. The validity of the model was determined using several metrics such as precision, recall, mean average precision (mAP), and inference time.

3.4 MODEL INFERENCE

After training, the inference process (A2 to C2) was conducted to evaluate each model's performance. As illustrated in Figure 1, the inference pipeline consists of four key components: to detect people, the presence of hard hats, the colour of hard hats and the use of mobile phones. The first component of the pipeline is the YOLOv11-s person detection model, which detects (A2.1), localises (A2.2), and slices the matrix (A2.3) to isolate ROI1 (the detected person) from the full image. This step provided the subsequent detections with enlarged ROI focusing only on relevant regions.

The sliced matrix is passed through the hard hat detection model, which detects (B2.1) and localises (B2.2) hard hats within the ROI. After localisation, the hard hat region undergoes image preprocessing (B2.3 to B2.8) to determine its colour accurately. Due to varying lighting conditions, detecting a fixed hard hat colour was challenging, as some areas of the hard hat appeared shinier or darker than others. The Red-Green-Blue (RGB) colour scale relies on fixed values, which are suitable for consistent lighting conditions. However, inconsistent lighting caused by environmental factors made the RGB-based colour scale unsuitable for this model. To overcome this limitation, this study used the Hue-Saturation-Value (HSV), which employs a range of values to define colours. By applying histogram analysis, the primary colour of the hard hat was determined based on the HSV range it belonged to. As shown in Figure 3, the central part of the upper half of the ROI was focused (B2.3), lighting and contrast were adjusted (B2.4), and its HSV values were extracted (B2.5). A histogram analysis (B2.6) was then performed to detect the colour (B2.7) and classify the hard hat as either "yellow hard hat" or "no yellow hard hat" (B2.8).

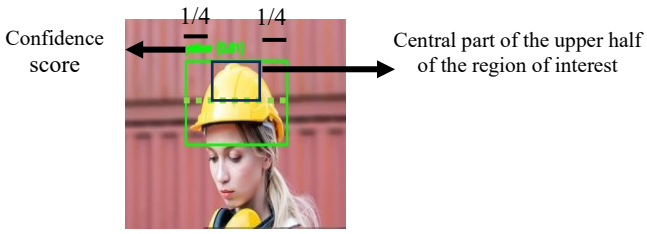

Figure 3:Region of interest

After the hard hat detection, the processed image was passed through the YOLOv11-s mobile phone detection model (C2). This model detects the presence or absence of a mobile phone (C2.1), highlighting whether a labourer is using a mobile phone in the image. Finally, the pixels in the original image were replaced with the processed image containing the detected elements. Here, the original image is displayed with the detections made.

3.5 MODEL DEPLOYMENT VALIDATION

The model was validated using images obtained from Sri Lankan construction sites (D) to assess its applicability within the Sri Lankan context and to check for potential overfitting.

4. RESULTS AND PERFORMANCE EVALUATION

4.1 CONFUSION MATRIX

A confusion matrix of 2x2 classifiers determines the predicted and actual classification. Table 3 provides the details of a 2x2 confusion matrix, which provides the relationship between true positives, false positives, true negatives and false negatives. As shown in Figure 2, the model provides a confidence score for the certainty of its detection, which plays a crucial role in identifying the false negative and false positive labels (Wenkel et al., 2021). In this study, a confusion matrix was generated only for the hard hat detection model, which performed detection and classification.

Table 3: Standard Confusion Matrix

	Actual Positive	**Actual Negative**
Predicted Positive	True Positive (TP)	False Positive (FP)
Predicted Negative	False Negative (FN)	True Negative (TN)

Figure 4 provides the normalised confusion matrix of the hard hat detection model, which detects two classes: hard hat and no hard hat. The values are normalised to represent the proportion of the outcome instead of raw counts, which undergoe object detection and classification. The values are normalised to represent the proportion of the outcome instead of raw counts. The matrix indicates 95% accuracy for hard hat detection and 90% accuracy for no-hard hat detection, with significantly low false positive and false negative rates.

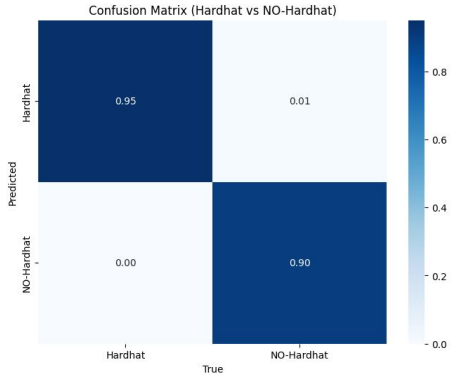

Figure 4: Normalised confusion matrix for hard hat classification

4.2 PRECISION-RECALL CURVE

Precision measures the ratio of true positive detections to the total positive detections made (see Equation 1). This reflects the ability of the model to accurately classify “hard hat” or “no-hard hat” without generating false detections. A high precision score indicates a lower rate of false detection. Meanwhile, recall measures the ratio of true positive detection to the total actual positive labels (see equation 2). It indicates how well positives

are recalled. A high recall score indicates that the model is effective in detecting the relevant instances.

$$Precision = \frac{TP}{TP+FP} \quad Equation\ (1) \qquad Recall = \frac{TP}{TP+FN} \quad Equation\ (2)$$

To achieve high prediction accuracy, it is crucial to maintain a balance between precision and recall. A model with high precision but low recall is very accurate in its positive predictions but misses a significant number of actual positive labels, while high recall but low precision may lead to excessive false positives. Therefore, a precision-recall (PR) curve for each detection task illustrates how well the model trades off these values.

The PR curve in Figure 5 shows the balance between precision and recall for the person detection model. Accordingly, the model achieved a high precision at a lower recall value, indicating a high probability of correct positive prediction. As the recall value increases, the false positive prediction also increases. The PR score for the person detection model was 0.826, indicating that the model correctly detects 82.6% of the actual instances. Similarly, the PR curve for hard hat detection in Figure 6 demonstrates high precision-recall scores, with 0.933 for hard hat detection and 0.927 for no-hard hat detection. The model maintains high precision across most recall values. This indicates the model can correctly classify hard hats while minimising false positives. Finally, Figure 7 presents the precision-recall curve for mobile phone detection, which also indicates a high PR value of 0.916, indicating that the model correctly detects 91.6% of the actual instances.

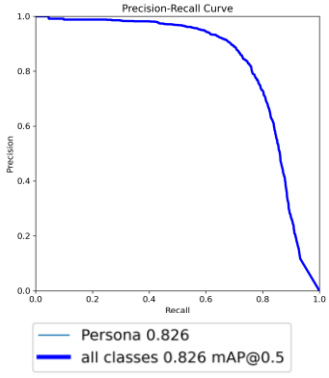

Figure 5: Precision-Recall curve for person detection

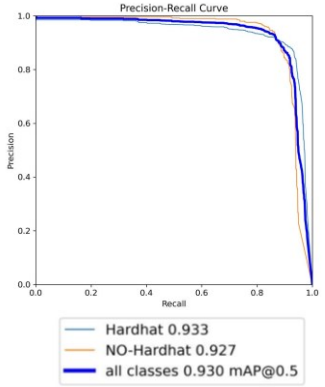

Figure 6: Precision-Recall curve for hard hat detection model

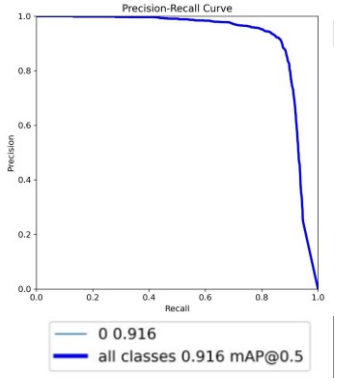

Figure 7: Precision-Recall curve for mobile phone detection

4.3 MEAN AVERAGE PRECISION (MAP)

The mAP calculates the average precision across multiple Intersections over Union (IoU) thresholds. Here, mAP@0.5 was calculated, where the average precision was calculated at a threshold of 0.5. This evaluated the accuracy of the classification.

$$mAP@0.5 = \frac{1}{number\ of\ classes\ (n)} \sum_{i=1}^{n.} Average\ Precision \quad Equation\ (3)$$

According to Figures 5, 6, and 7, the mAP@0.5 of the person detection model, hard hat detection model, and mobile phone detection model were 0.826, 0.930, and 0.916, respectively. These results indicate that each model achieved a high detection accuracy, with scores exceeding the identified threshold values. The hard hat detection model showed the highest performance among the trained models. These results infer that the trained models can provide accurate detection in construction site environments.

4.4 INFERENCE TIME

Inference refers to the process of using a trained model to make predictions on new, unseen data by processing an image and generating detection results. The inference time of the model measures the average time taken by the YOLOv11-s model to process a single image and generate the detection results. The YOLOv11-s model demonstrated fast inference times, with the person detection model achieving the quickest processing of 4.9ms. The hard hat detection model took 8.5ms, which is slightly longer due to the added classification of hard hat and no-hard hat classes. Similarly, the mobile phone detection model had an inference time of 8.4ms, due to the additional processing required for detecting smaller objects. All three models demonstrated a fast-processing time which indicated that the model is suitable for real-time application.

4.5 TRAINING AND VALIDATION LOSS

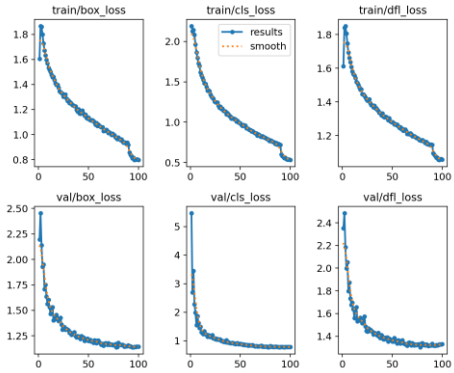

Figure 8: Training and validation loss curve for person detection

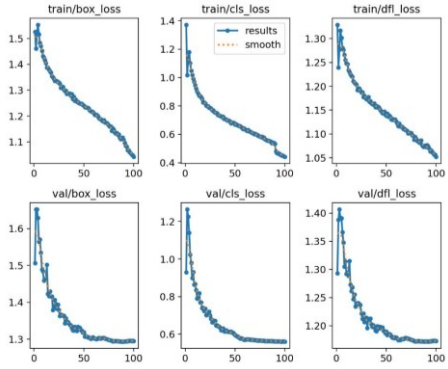

Figure 9: Training and validation loss curve for hard hat classification

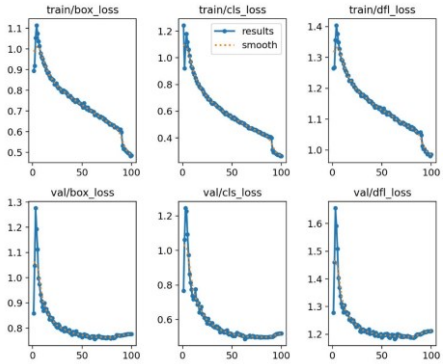

Figure 10: Training and validation loss curve for mobile phone detection

Furthermore, the loss function, also referred to as the error function, quantifies the error between the algorithm's predicted output and the actual output. The YOLOv11-s model uses a unified loss function, which is a combination of three loss components. This includes Complete Intersection over Union loss (CioU), Binary Cross Entropy Loss (BCE) and Distribution Focal Loss (DFL). CioU is used for the bounding box regression (box_loss) (Zheng et al., 2021), BCE is used for the classification (cls_loss) (Li et al., 2024)and DFL is used for better localisation accuracy by refining the predicted bounding box coordination (dfl_loss) (Wang et al., 2023).

Figures 8, 9 and 10 provide the training and validation loss curves recorded during the model's training in person detection, hard hat classification and mobile phone detection. As the number of epochs increased, the loss function steadily decreased indicating an

effective learning and optimisation by the model. Similarly, the precision, recall and mAP metrics exhibited a steady increase over epochs, reinforcing the model's improving performance. The model's stable performance suggests high reliability in classifying hard hat and no-hard hat cases.

4.6 MODEL DETECTIONS

Figure 11 presents the detections performed by the model across various conditions during the testing phase. Here the detection is indicated with a bounding box and a confidence score which demonstrates the level of certainty of the model in making the detection.

4.7 MODEL DEPLOYMENT IN THE SRI LANKAN CONTEXT

The model was tested with custom images obtained from Sri Lankan construction sites, captured with cameras and mobile phones to validate its deployment performance and to check for model overfitting. The Sri Lankan construction site dataset included images taken from distant locations, where the person detection model and matrix slicing played a crucial role in enlarging the ROI for subsequent detections. After detecting the mobile phone, the processed image was refitted to the original image using its initial coordinates with detection results as shown in Figure 12 to Figure 14.

Figure 14: Construction labourer without helmet and with mobile phone

5. CONCLUSIONS AND RECOMMENDATIONS

This study presented an analysis of the YOLOv11-s model in the detection of mobile phone use by construction labourers. The use of YOLOv11-s has demonstrated faster processing by structuring detection into four components: (1) detection of people, (2) detection and classification of hard hats, (3) image processing to detect hard hat colour and (4) mobile phone detection. Training, internal validation and testing of the model were done using datasets obtained from an online database. The model was externally validated for deployment using custom images obtained from Sri Lankan construction sites and checked for potential overfitting. With high inference speed and accuracy, the model indicated a satisfactory level of applicability to the Sri Lankan context and proved to be a solution for construction projects concerned with productivity challenges caused by mobile phone distractions among labourers. While the system was tested on Sri Lankan site images for the deployment, the methodology and model architecture are universally applicable across global construction environments. Even though the model demonstrated a satisfactory level of accuracy, the detection accuracy may vary depending on external factors such as dust levels in surroundings, weather conditions, detection

distance, and the quality of captured photos, which is a limitation of this study. Therefore, future research can focus on enhancing the proposed model by training it with a large set of Sri Lankan images captured under diverse environmental conditions and lighting variations to improve its reliability. Additionally, the model can be developed to detect continuous mobile phone usage among site labourers through motion detection and timeframe analysis using the Internet of Things (IoT). This would enable the model to monitor frequent and prolonged mobile phone usage from CCTV footage, providing real-time alerts to supervisors to enhance productivity on construction sites.

DEVELOPING A KNOWLEDGE VALUE CHAIN FRAMEWORK FOR TENDERING IN SRI LANKAN CONSTRUCTION ORGANIZATIONS

Lebunu Hewage Udara Willhelm Abeydeera[1], Jayantha Wadu Mesthrige[2] and A.S.W. Karunarathna[3]

ABSTRACT

The construction industry in Sri Lanka, like many in developing nations, faces persistent inefficiencies in tendering processes due to fragmented knowledge practices and inadequate knowledge management systems. This study presents the preliminary findings of a broader research project aimed at developing an advanced Knowledge Value Chain Management (KVCM) framework to address these challenges. Drawing on both theoretical underpinnings and empirical insights, the research critiques the limitations of existing tendering models for the purpose of developing a KVCM framework to structure, process, and leverage organizational knowledge. Preliminary insights suggest that successful integration of the KVC approach requires not only process-level adjustments but also a cultural and infrastructural shift toward strategic knowledge sharing and ICT-enabled systems. This paper forms part of an ongoing research initiative that culminates in the formulation of a comprehensive, context-sensitive KVCM model for the Sri Lankan construction sector. By bridging knowledge management principles with tendering strategy, this study contributes to the emerging discourse on knowledge-based competitiveness in project-driven industries. It underscores the strategic potential of KVC integration to foster institutional memory, improve tendering efficiency, and support sustainable organizational learning in developing construction markets. This contribution advances the discourse on knowledge management in project-based industries and underscores the strategic role of knowledge as an asset in competitive tendering environments.

Keywords: *Knowledge Value Chain Management; Quantity Surveyors'; Construction; Sri Lanka; Tendering.*

1. INTRODUCTION

Knowledge Management (KM) has evolved as a critical discipline within organizational theory, particularly since the 1990s, emphasizing the strategic role of knowledge as a core asset for competitive advantage (Nonaka & Takeuchi, 2023). In construction, where

[1] PhD Candidate, School of Property, Construction and Project Management, RMIT University, Australia, S3855817@student.rmit.edu.au

[3] Temporary Lecturer, Department of Facilities Management, University of Moratuwa, Sri Lanka, sandunik@uom.lk

projects are unique and temporally bound, KM is especially important for capturing, codifying, and transferring valuable project knowledge to enhance future project outcomes. The development of Knowledge Value Chain Models (KVCMs), such as those building on Porter's foundational Value Chain framework (Porter, 2008), has further advanced the structured management of knowledge. Many studies (De Bem Machado et al., 2022; Di Vaio et al., 2021; Gallupe, 2001) have investigated the concepts of knowledge, KM, and KVCMs from an organizational perspective. KVCMs in construction are tailored frameworks that map the flow of knowledge across project stages, ensuring that valuable insights gained are not only retained but systematically used to optimize performance and improve tendering processes (Baia et al., 2020). However, existing KVCMs are generally designed with a broad organizational focus, leaving a gap in literature regarding their application to the specific knowledge value creation within the tendering process of construction organizations, particularly in relation to quantity surveying.

The construction industry, particularly in developing economies such as Sri Lanka, is knowledge-intensive and increasingly reliant on the effective mobilization of intellectual capital for competitive advantage. Among key professionals, Quantity Surveyors (QSs) play a central role in cost control, tender evaluation, and contract administration, functions that depend heavily on the systematic creation, sharing, and utilization of knowledge. As construction projects become more complex and time-bound, the ability to manage this knowledge efficiently across the tendering phase has become critical. This shift underscores the growing relevance of KVCM frameworks which aim to optimize knowledge flows to enhance organizational performance and strategic positioning. Globally, research has demonstrated the utility of KVCM in refining construction processes, particularly tendering, through structured knowledge governance. Dewagoda et al. (2021) proposed a KVCM framework explicitly for contractor organizations, emphasizing how knowledge processes can increase the probability of winning tenders and improve decision-making efficacy. However, such frameworks are typically conceptualized in broader corporate or regional contexts, with minimal focus on the nuanced operational roles played by QSs in emerging economies.

In the Sri Lankan context, knowledge management among QSs has largely been limited to ad hoc practices. Senaratne and Sabesan (2010) found that while QSs in Sri Lanka are competent in applying experiential knowledge, systemic barriers such as poor institutional support, time constraints, and limited professional recognition hinder knowledge acquisition and dissemination. Moreover, existing research have not addressed how structural and cultural constraints unique to Sri Lanka impede the implementation of formal KVCM approaches during tendering. While Perera and Gunatilake (2022) discussed the broader inefficiencies in Sri Lanka's construction value chains, their work did not explore tendering-specific dynamics or the QS's knowledge role therein.

This paper aims to explore the preliminary conditions necessary for the development of a Knowledge Value Chain Management framework tailored to the tendering processes of Sri Lankan construction organizations. As a foundational phase of a broader research project, the study seeks to critically examine current knowledge practices, identify barriers to effective knowledge management, and assess the applicability of existing KVC models within the local tendering context. Specifically, the objectives are: (1) to investigate how knowledge is created, shared, and utilized by Quantity Surveyors and

other professionals during tendering; (2) to evaluate the strategic role of knowledge in achieving competitive advantage in construction tendering; and (3) to identify structural, cultural, and operational constraints that influence the integration of KVC principles in practice. These insights serve as the empirical and conceptual groundwork for the subsequent development of a comprehensive, context-sensitive KVCM framework aimed at enhancing organizational learning and decision-making in Sri Lanka's construction sector.

2. LITERATURE REVIEW

2.1 EVOLUTION OF KM IN CONSTRUCTION

KM has evolved through three distinct generations, reflecting a shift from information-centric systems to strategic, value-driven frameworks. In the first generation, KM was primarily technical, focusing on the codification and storage of explicit knowledge through databases and intranets. However, this approach inadequately addressed the tacit, experience-based knowledge crucial in project-based industries like construction (Rezgui et al., 2010). The second-generation approaches emphasized social interaction and knowledge sharing, introducing mechanisms such as communities of practice and mentoring. In construction, this generation aligned more closely with the industry's collaborative nature, where cross-functional teams must exchange expertise across fragmented project cycles (Anumba & Pulsifer, 2010). The third generation of KM focuses on strategic alignment and value creation, positioning knowledge as a dynamic capability rather than a static resource. It integrates KM into innovation, performance improvement, and organizational competitiveness, critical in today's complex construction environments (Chen & Fong, 2013).

Despite these advances, the construction sector remains one of the more challenging environments for KM implementation. The fragmented supply chains, short-term contractual relationships, and diversity of stakeholders pose systemic barriers to KM maturity (Egwunatum & Oboreh, 2022). These barriers are especially pronounced in small to medium-sized firms, which lack the resources to implement sophisticated KM systems. Furthermore, the emphasis on project delivery over organizational learning continues to marginalize KM in many construction enterprises. The evolution of KM has laid a conceptual and operational foundation for the emergence of KVCM models. As KM transitioned from static knowledge repositories to dynamic, value-oriented systems, scholars recognized the need to map knowledge processes directly to organizational performance outcomes (Rezgui et al., 2010). This realization gave rise to the KVCM approach, which integrates KM activities into a chain of interrelated processes that collectively generate measurable business value (Boamah et al., 2022). In project-based industries like construction, where knowledge must be continuously created, contextualized, and applied across shifting teams and time-bound deliverables, KVCM offers a structured methodology to convert intellectual capital into strategic advantage (Dewagoda et al., 2021). Thus, KVCM can be understood as an advanced extension of KM, bridging the gap between knowledge practice and value realization in complex, knowledge-intensive sectors.

2.2 KNOWLEDGE VALUE CHAIN MODELS

KVCMs are structured frameworks that outline the processes through which knowledge is created, shared, and applied within organizations. One of the foundational models was introduced by Porter (1985) in his Value Chain framework, which highlighted how value is created through a series of primary and support activities. Adapted for KM, KVCMs emphasize the flow and transformation of knowledge across different stages, such as knowledge creation, storage, sharing, and utilization. These stages are essential for capturing both explicit and tacit knowledge, ensuring that valuable insights from past projects or organizational experiences are effectively leveraged. The application of KVCMs in KM practices can foster better decision-making, innovation, and overall organizational learning, particularly in knowledge-intensive industries like construction (Rezgui, 2001). However, the effectiveness of KVCMs depends on their integration into organizational structures and the willingness of individuals to contribute their knowledge to these systems.

A key aspect of KVCMs is their focus on knowledge creation and dissemination, often facilitated by advanced technologies such as knowledge management systems (KMS). Dalmarco et al. (2017) argue that effective KVCMs not only capture knowledge but also enhance knowledge sharing across departments, reducing silos and promoting organizational cohesion. By structuring knowledge flows, KVCMs ensure that both tacit and explicit knowledge are accessible for decision-making processes, contributing to competitive advantage. However, despite their benefits, the challenge often lies in the codification of tacit knowledge, experiential, often unspoken insights that are difficult to formalize (Nonaka & Takeuchi, 2007). Construction organizations, for instance, struggle with capturing the vast amounts of tacit knowledge generated through project experiences, which is critical for maintaining continuity between projects (Carrillo et al., 2013). KVCMs have evolved significantly since Porter's seminal work in 1985, which introduced a framework for analysing competitive advantage by examining primary and support activities within organizations. Over time, these models have adapted to include critical aspects of KM and digital transformation, which are increasingly important in today's data-driven business environments. Table 1 provides a summary of five key KVCMs that have been recognized through the literature. These models have played a key role in the evolvement of knowledge management in the construction industry.

Table 1: KVCMs developed over the years

	Reference	Model summary
1	(Porter, 1985)	This model identifies primary (inbound logistics, operations, outbound logistics, marketing and sales, and service) and support activities (firm infrastructure, human resource management, technology development, and procurement) to analyse competitive advantage.
2	(Alavi & Leidner, 2001)	This model applies value chain logic to knowledge, focusing on stages such as acquisition, codification, transfer, and application to optimize the creation and utilization of knowledge within organizations.
3	(Stankosky, 2005)	This model extends KM principles by focusing on knowledge flow and transformation within organizations,

	Reference	Model summary
		advancing from data to information, knowledge, and wisdom to support strategic decision-making.
4	(Lambert & Cooper, 2000)	This model adds customer and supplier relationship management to traditional value chain analysis, reflecting modern supply chain complexities.
5	(Bharadwaj et al., 2013)	This model adapts value chain concepts for digital business, emphasizing data-driven processes and digital resources, enhancing efficiency and responsiveness in real-time market dynamics.

In developed economies, the application of KVCMs has been linked to enhanced project integration, transparency, and innovation. Organizations benefit from ICT-enabled knowledge flows, organizational learning cultures, and institutional incentives. In contrast, the implementation of KVCs in developing countries often suffers from significant structural deficiencies. These include limited digital infrastructure, fragmented project teams, and the absence of formal knowledge-sharing mechanisms. Such inefficiencies constrain the conversion of knowledge into actionable project outcomes, contributing to cost overruns and tendering inefficiencies (Senaratne & Sabesan, 2010). Sri Lanka exemplifies this disparity. Despite the growing strategic role of Quantity Surveyors in managing cost and risk, KVCM adoption remains embryonic. Studies reveal knowledge-sharing mechanisms are informal, often limited to individual initiative, with minimal institutional support or sector-wide frameworks (Perera & Gunatilake, 2022). These systemic gaps highlight a pressing need for a context-specific KVC model tailored to Sri Lanka's construction environment. This study addresses that lacuna by critically exploring the preconditions necessary for meaningful KVC integration in tendering processes.

3. RESEARCH METHODOLOGY

This study adopts a qualitative, interpretivist (constructivist) research paradigm to investigate how knowledge is generated, shared, and applied in tendering processes within Sri Lankan construction organizations. The interpretivist approach, which focuses on understanding subjective meanings and contextualized practices, is well-suited for exploring the complex, tacit nature of knowledge in construction tendering settings (Creswell & Creswell, 2017).

3.1 RESEARCH DESIGN AND RATIONALE

Given the exploratory nature of the study and the limited literature on KVCM in construction tendering, a qualitative approach was selected. This design enables deep engagement with the perspectives of QSs, and other professionals involved in the tendering process. The study specifically focuses on the contractor-side perspective, as contractors are primarily responsible for operationalizing knowledge in competitive bidding and pricing strategies. Two qualitative methods were employed: semi-structured expert interviews and multiple case studies. The combination enhances methodological triangulation and allows for both depth (through interviews) and context (through organizational case analysis) as recommended in exploratory construction research (Yin, 2009).

3.1.1 Phase I: Expert Interviews

Semi-structured interviews were conducted with ten purposefully selected professionals (Table 2). Participants were selected using purposive sampling based on three criteria:

- Minimum of 10 years of experience in tendering/contract management.
- Chartered status or senior executive position.
- Involvement in contractor-side tendering decisions.

This selection ensured that participants possessed in-depth practical knowledge of tendering knowledge practices. The semi-structured format enabled consistent inquiry while allowing exploration of emergent themes (Adeoye-Olatunde & Olenik, 2021).

Table 2: Expert interviewee profiles

Code	Designation	Experience	
		Years	Key Experience
PI.01	Claims Consultant	20	Tendering, Claims Management, Project Management
PI.02	Freelancer QS	30	Tendering, Tender Negotiation, Project Administration
PI.03	Chief QS	20	Tendering, Contract Management, Project Administration
PI.04	Director	43	Tendering, Tender Evaluation, Contract Management
PI.05	Assistant General Manager	11	Tendering, Tender Negotiation, Project Administration
PI.06	Senior Lecturer	26	Tendering, Claims Management, Commercial Management, Forensic Delay Analysis
PI.07	Senior QS	20	Tender Evaluation, Consulting, Project Administration
PI.08	Managing Director	35	Tendering, Tender Negotiation, Contract Management
PI.09	Chairman	20	Tendering, Project Administration, Contract Management
PI.10	Senior QS	20	Tender Evaluation, Consulting, Project Administration

3.1.2 Data Analysis and Validation

Interview transcripts were analysed using manual content analysis, allowing for inductive theme identification with attention to contextual meaning (Mayring, 2021; Salmona & Kaczynski, 2024). Key themes included knowledge creation, sharing mechanisms, barriers, and perceived value across the tendering lifecycle.

To ensure rigor, the following validation strategies were implemented:

- Construct Validity: Achieved through triangulation of interviews and document reviews (Yin, 2009)
- Internal Validity: Enhanced via pattern matching between expected and emergent themes (Takada et al., 2021)

- Reliability: Ensured through standardized interview protocols and systematic transcript archiving (Wong et al., 2023)

4. FINDINGS AND DISCUSSION

This section presents and critically analyses the findings from Phase I of the research, which involved expert interviews aimed at informing the development of a Knowledge Value Chain Management framework for tendering in Sri Lankan construction organizations. Data were obtained from ten semi-structured interviews with Chartered Quantity Surveyors and senior professionals (see Table 2). The themes discussed here are directly derived from interview data and interpreted in relation to the research objectives. Quotations from participants are coded as PI.01 to PI.10.

4.1 THE KNOWLEDGE-INTENSIVE NATURE OF CONSTRUCTION

Participants unanimously agreed that the construction industry is inherently knowledge-intensive due to its complex and dynamic nature. PI.03 noted, "Every tendering decision we make depends on how well we understand the site, client, and contractual environment." The fast pace of technological change and the multifaceted nature of projects demand continuous learning and information flow. This finding reinforces the notion that effective knowledge practices are vital to navigating risk and uncertainty in project environments. Unlike prior literature that generalizes the importance of KM (Nonaka & Takeuchi, 2007), this study emphasizes that the demand for knowledge specificity is especially acute in tendering contexts.

4.2 STRATEGIC USE OF TENDERING APPROACHES

Interviewees highlighted two dominant strategies in tendering: cost leadership and differentiation. Cost leadership is more prevalent in public-sector projects, while differentiation is pursued in private-sector tenders. However, PI.06 emphasized that "real differentiation comes not just from price, but from how we propose to execute and manage the job." These findings nuance Carrillo et al.'s (2013) framework by indicating that strategic deployment is often bid-phase specific and shaped by institutional expectations. Moreover, the interviews revealed a lack of formal integration between strategic intent and knowledge processes, which creates inefficiencies in adapting tendering strategies.

4.3 ROLE OF TACIT KNOWLEDGE IN COMPETITIVE ADVANTAGE

Interviewees consistently emphasized the significance of tacit knowledge in enhancing organizational competitiveness. PI.01 stated, "You can't teach someone how to price intuition, you learn it on the job." The data revealed that practical experience, intuition, and context-sensitive knowledge play a dominant role in shaping tender outcomes. This insight echoes Hanisch et al. (2009), but the study adds granularity by showing how tacit knowledge is often internalized by senior QSs and not effectively transferred within teams. This knowledge asymmetry creates strategic vulnerabilities for firms.

4.4 ORGANIZATIONAL LEARNING AND KNOWLEDGE REUSE

Participants strongly supported the idea that construction organizations function as learning entities. PI.08 observed, "Each project teaches us something new, but we often fail to document or apply that knowledge." The absence of formalized feedback loops leads to repeated mistakes and lost insights. While Darwin (2017) advocates for structured learning in project cycles, the data here suggest that although professionals value learning, organizations lack mechanisms to operationalize it. This presents a critical area where KVCM could improve tendering performance.

4.5 STRATEGIC ROLE OF QUANTITY SURVEYORS

QSs were unanimously acknowledged as central to the competitive success of construction firms. According to PI.02, "The QS is the one who converts the project vision into numbers, it's both an art and a science." Their dual role in cost control and value optimization underscores their importance as knowledge brokers. This supports Mbachu (2015), but the present study contributes further by highlighting how QSs must navigate between managerial and knowledge-intensive roles, making them pivotal in KVC deployment.

4.6 QSS AS KNOWLEDGE WORKERS AND DECISION MAKERS

Interviewees offered nuanced perspectives on classifying QSs as Knowledge Workers (KW) or Decision Makers (DM). PI.09 stated, "Even junior QSs make decisions, maybe not strategic ones, but operationally critical ones." This suggests a fluid continuum where roles shift based on context and experience. This challenges Powell's (2001) rigid categorization and emphasizes the need for adaptable role definitions in KVCM models tailored for construction.

4.7 APPLICABILITY OF THE KVCM IN TENDERING

Participants expressed strong support for the KVCM concept. PI.04 stated, "We badly need a model that helps us align our experience, lessons learned, and market understanding with each new bid." The model was seen as a practical tool for minimizing redundancy, improving pricing strategies, and fostering learning. While Alavi and Leidner (2001) underscore the benefits of structured KM systems, this study provides empirical validation from a Sri Lankan context, highlighting both the necessity and feasibility of KVCM in enhancing tendering effectiveness.

4.8 BARRIERS TO KVCM IMPLEMENTATION

Several barriers to KVCM implementation emerged from the interviews. While these challenges are situated within the Sri Lankan construction context, they are emblematic of broader trends observed across developing and transitional economies in the construction sector, suggesting that the findings are both context-specific and generalizable to comparable settings. A recurrent theme is the misalignment between formal knowledge systems and existing organizational structures. Specifically, the fragmentation of KVCs and the marginalization of enabling systems reflect a structural rigidity commonly observed in project-based industries. Dewagoda et al. (2021) identified this lack of integration as a barrier to optimizing knowledge as a competitive asset in contractor organizations, underscoring the importance of cohesive systems that facilitate knowledge continuity across the tendering lifecycle.

Behavioural and cultural resistance emerges as another critical barrier. This includes scepticism toward knowledge outputs, disregard for feedback mechanisms, and an entrenched focus on traditional roles. These cultural barriers are not unique to Sri Lanka but are well documented in global construction knowledge management studies. As noted by Senaratne and Sabesan (2010), there exists a strong reluctance to share knowledge due to professional insecurities and a lack of systemic incentives, resulting in poor dissemination and underutilization of institutional knowledge. Furthermore, Mahinkanda et al. (2019) highlight the difficulty of bridging the theory-practice gap in value management frameworks due to resistance to new ideas, inadequate training, and minimal support for professional development in knowledge-based roles.

Operational constraints, namely time and cost limitations, were universally acknowledged across all data sources. These are symptomatic of the fast-paced, budget-restricted nature of construction tendering worldwide. The literature emphasizes that KWs, such as quantity surveyors, are often "running against time," which inhibits the adoption of reflective and systematic knowledge practices (Senaratne & Sabesan, 2010). These conditions are mirrored in other studies that link tight project cycles with poor uptake of long-term knowledge strategies. Human resource constraints also appear to have wide relevance. The shortage of skilled professionals with dual competencies in construction and knowledge management has been highlighted as a structural gap, both in Sri Lanka and in other developing regions. Senaratne and Sabesan (2010) emphasized that the emigration of experienced quantity surveyors and the undervaluation of their roles within local firms leads to a weakened knowledge base and diminished opportunities for mentoring and skill transmission.

Finally, the delayed realization of KVCM benefits reflects a broader industry challenge regarding innovation adoption. Without short-term measurable outcomes, organizations may lack the strategic foresight and patience to nurture knowledge ecosystems. This impatience is compounded by a narrow definition of "value" that favours immediate cost or time savings over intangible gains like learning, adaptability, or collaborative capacity. These findings, while grounded in Sri Lankan case studies, point to broader, cross-contextual insights. They underscore the need for an integrative approach to KVCM that encompasses not just technological enablers and formal processes, but also human, cultural, and institutional readiness. As such, the barriers presented are not anomalies but are reflective of deeper structural and behavioural tendencies within the global construction sector. Addressing them requires more than technical adjustments, it calls for a paradigmatic shift in how organizations perceive and operationalize knowledge.

5. CONCLUSION

This This study explored the preliminary conditions necessary for developing a KVCM framework tailored to the tendering processes of Sri Lankan construction organizations. Grounded in qualitative insights from expert interviews with senior Quantity Surveyors and construction professionals, the research examined how knowledge is created, shared, and utilized during tendering, and identified the structural, cultural, and operational factors that influence these practices.

The findings highlight that construction tendering in Sri Lanka is heavily reliant on tacit knowledge, with limited formal mechanisms for capturing and institutionalizing experiential learning. Despite recognition of the strategic value of knowledge in gaining

competitive advantage, organizations lack structured systems for knowledge reuse, resulting in inefficiencies and recurring errors. The study also reveals the dual role of QSs as both Knowledge Workers and Decision Makers, underscoring their pivotal function in shaping tender outcomes. Furthermore, interviewees affirmed the relevance and potential of the KVCM concept for enhancing knowledge-driven competitiveness, even though its practical adoption remains minimal.

This research contributes original, context-specific insights into the intersection of knowledge management and tendering strategy in a developing country context. It advances the understanding of QSs' evolving roles and provides empirical evidence supporting the applicability of KVCM principles in contractor-led tendering environments.

5.1 LIMITATIONS AND FUTURE RESEARCH

This paper represents Phase I of a broader research project. Phase II will involve in-depth case studies with C1-graded construction organizations to examine organizational-level practices and validate the findings. The future phase will culminate in the development of a conceptual KVCM framework specifically adapted to Sri Lankan contractor organizations, linking knowledge processes with decision-making across the tendering lifecycle.

This study is limited by its exclusive reliance on interview data, which, while rich in insight, may not fully capture organizational systems or informal practices across diverse firm sizes. Additionally, the sample was restricted to contractor-side professionals, limiting perspectives from consultants or clients. Future research should incorporate multi-stakeholder viewpoints and mixed methods to triangulate findings and generalize the model across different construction contexts.

DEVELOPING A SATELLITE-ENABLED DIGITAL TWIN ECOSYSTEM FRAMEWORK FOR ENERGY MONITORING IN SMART CITIES IN SRI LANKA: A LITERATURE REVIEW

Rusin Thathsara[1] and Harshini Mallawaarachchi[2]

ABSTRACT

Smart cities are at the forefront of sustainable urban development, yet energy monitoring remains a critical challenge for achieving efficiency and environmental goals. Current technologies, such as Internet of Things (IoT) and building management systems, often lack the city-wide perspective needed for comprehensive energy optimization. Similarly in Sri Lanka, energy consumption in smart cities presents a complex challenge, as urban areas account for a significant portion of global energy demand and contribute heavily to carbon emissions. Hence, effective real time energy monitoring is essential to enhance energy efficiency and reduce carbon emissions in smart cities. Among emerging technologies, the satellite-enabled digital twin ecosystem (SEDTE), powered by real-time satellite data, offers a transformative approach to energy monitoring. This study aimed proposing a satellite-enabled digital twin ecosystems (SEDTE) to enhance energy monitoring in smart cities in Sri Lanka. Accordingly, key peer-reviewed journal articles, conference papers, and reports published on satellite technology, digital twins, smart cities, energy monitoring and energy efficiency between 2015 and 2025 were comprehensively reviewed. As derived through literature review, data acquisition, real-time energy optimization, grid resilience, load balancing, demand response, renewable energy integration, and disaster preparedness of energy systems are the key applications of SEDTE in the context of smart city energy monitoring. Finally, a framework was proposed to adopt this advanced technology in the development of smart cities in Sri Lanka and similar settings as the key implication of the study.

Keywords: *Digital Twin Ecosystems; Energy Monitoring; Satellite Technology; Smart Cities; Urban Sustainability.*

1. INTRODUCTION

With cities growing rapidly, smart cities use advanced tech to boost efficiency and sustainability. Energy management is a key challenge, critical for cutting emissions and meeting climate goals. Smart cities rely on interconnected systems to manage energy across residential, commercial, and industrial sectors. Urban areas consume about 70%

[1] Undergraduate Student, Department of Building Economics, University of Moratuwa, Sri Lanka, rusinthathsaraofficial@gmail.com
[2] Senior Lecturer, Department of Facilities Management, University of Moratuwa, Sri Lanka, harshinim@uom.lk

of global energy and produce 75% of carbon emissions. Rising populations, electric vehicles, and tech like IoT devices drive complex energy demands. Consumption varies by area and time—think business districts peaking daytime versus homes at night. This variability, plus the shift to renewables like solar, demands precise monitoring to avoid waste and ensure grid stability (Batty, 2018).

Monitoring energy use is vital for sustainable smart cities. It helps spot inefficiencies, balance supply and demand, and cut emissions. Real-time data supports strategies like dynamic pricing, easing grid stress (Mohammadi & Taylor, 2017). It also aligns with UN Sustainable Development Goals (SDGs 7 and 11) and aids renewable energy integration, like rooftop solar. At present, smart meters, building management systems (BMS) and graphic information systems (GIS) are applied for monitoring energy consumption in buildings and urban infrastructure, while ground-based remote sensing and IoT sensors have become increasingly popular (Alahakoon & Yu, 2016; Ejaz et al., 2017; Yamagata & Seya, 2013). However, these tools work well in isolation but lack the integration needed for city-wide, real-time monitoring, highlighting the need for solutions like digital twins (Qi et al., 2021). Satellite-enabled digital twins' virtual representations of urban systems enhanced by real-time satellite data which provide a revolutionary approach to monitor energy consumption. These systems provide city-wide insights and predictive tools (Tao et al., 2019; Sharma et al., 2024). The satellite-enabled digital twins system combines satellite imagery and virtual modelling to track city energy systems. Further, this technology can be used to monitor the entire city, detecting heat losses and solar efficiency. Possibility of integrating real-time data to predict energy demand or failures, cost effective use for diverse cities application of dashboard-aided planning can be highlighted as key benefits of the satellite-enabled digital twins ecosystem (SEDTE) which signifies the use of satellite-enabled digital twins for monitoring performance of building and infrastructure (Qi et al., 2021). Although several studies have been conducted on artificial intelligence, digital twins, energy monitoring and smart cities (Sghiri et al., 2025; Sayed et al., 2025; Noori et al., 2025), it is seldom in prevailing research studies that applying satellite-enabled digital twins for energy monitoring in smart cities. Similarly, the smart city in Sri Lanka also lacks modern energy monitoring mechanisms, thus exclaim the need of integrating with SDETE. Hence, the need to investigate how SEDTE can be applied for energy monitoring in smart cities was considered as the point of departure for this research. Hence, this study aims at developing a satellite-enabled digital twin ecosystem (conceptual) model for energy monitoring in smart cities in Sri Lanka. As the initial step, this paper aimed at achieving two (02) objectives as: (i) Review the concept of satellite-enabled digital twin ecosystem, its applications for energy monitoring in smart cities, (ii) Propose a conceptual framework of SEDTE for energy monitoring in smart cities in Sri Lanka.

The methodology adapted is explained subsequently.

2. RESEARCH METHODOLOGY

This research aims at developing a satellite-enabled digital twin ecosystem (conceptual) model for energy monitoring in smart cities in Sri Lanka answering the research question "how SEDTE can be applied for energy monitoring in smart cities in Sri Lanka?". Hence, qualitative approach was adopted. Accordingly, a non-systematic literature review was adopted as the methodological foundation for the present study. Non-systematic reviews are often referred to as narrative reviews in academic literature. These reviews aim to

identify, synthesise, and summarise existing published work while also highlighting potential research gaps for future investigation (Ferrari, 2015). Further to the author, non-systematic reviews provide a theoretical and conceptual overview of the state of knowledge in a particular research area.

Hence, a non-systematic literature review was conducted on the satellite-enabled digital twin ecosystems (SEDTE) and its application for energy monitoring in smart cities. As this is new technology, due to limited literature, available key research papers were selected and reviewed to synthesise key insights, highlighting the research gap. Accordingly, key peer-reviewed journal articles, conference papers, and reports published on satellite technology, digital twins, smart cities, energy monitoring and energy efficiency between 2015 and 2025 in databases such as IEEE Xplore, ScienceDirect, Scopus, and Google Scholar and written in English were comprehensively reviewed. The search string was developed using the key words, such as Satellite-enabled digital twin ecosystems or SEDTE; Applications, Strategies, Energy monitoring and Smart cities. Themes were developed iteratively, guided by the review's objectives: understanding technological capabilities, applications and benefits. The review is limited by its reliance on published literature, which may exclude emerging but unpublished SEDTE applications.

3. SATELLITE-ENABLED DIGITAL TWIN ECOSYSTEM

A satellite-enabled digital twin ecosystem (SEDTE) is a sophisticated framework that integrates real-time satellite data with digital twins which can be used to enhance energy monitoring in smart cities. Digital twins are dynamic models that could mirror physical assets, such as buildings, energy grids etc, using data to simulate and optimise performance (Tao et al., 2019). SEDTE encompasses this concept by integrating satellite-driven data, such as weather, solar radiation, and air quality to provide a city-wide analysis on energy consumption. Unlike traditional systems, such as BMS, which focus on localised data, SEDTE provides a holistic view enabling predictive energy management and reducing carbon emissions (Deren et al., 2021). This ecosystem is essential for smart cities, where complex energy demands require scalable, real-time solutions to achieve efficiency and resilience (Ketzler et al., 2020).

3.1 SYSTEM INPUTS AND OPERATION

The SEDTE operates by processing diverse data inputs through advanced analytics to monitor and optimise building performance including energy consumption. According to key literature (Alahakoon & Yu, 2016; Yamagata & Seya, 2013), the key inputs of SEDTE include:

- Satellite data: This incorporates real-time data from low-earth orbit satellites, including high-resolution imagery, weather patterns, solar radiation, and air quality metrices. These data enable city-wide monitoring of energy related factors including heat losses and solar panel efficiency.
- Terrestrial data: This includes IoT sensors, smart meters and BMS, which provide building level insights, such as HVAC usage, lighting demands, occupancy patters etc.

- Contextual data: This considers urban planning data, energy grid performance and socio-economic factors (population density etc) which contextualise the energy needs across cities.

Operationally, SEDTE integrates these inputs into a unified digital twin platform, often powered by machine learning algorithms like Neural Networks or Random Forest. These algorithms analyse patterns to predict demand spikes, identify inefficiencies, and recommend optimizations, such as adjusting HVAC based on solar data or stabilizing grids with renewable energy inputs (Qi et al., 2021). Key functional capabilities include:

Real-Time Monitoring: Dashboards visualize energy trends, aiding stakeholders in decision-making (Deren et al., 2021), Predictive Analytics, such as forecasts energy needs and equipment failures, reducing waste by 15-25% (Sharma et al., 2024), and Scalability that covers entire cities cost-effectively, unlike localized systems (Ketzler et al., 2020).

4. SATELLITE-ENABLED DIGITAL TWIN ECOSYSTEM FOR ENERGY MONITORING

4.1 ENERGY CONSUMPTION AND MONITORING IN SMART CITIES

Energy consumption in smart cities poses a complex challenge, with urban areas accounting for approximately 70% of global energy demand and contributing to 75% of carbon emissions (International Energy Agency [IEA], 2023). This significant energy footprint stems from diverse sectors, including residential, commercial, industrial, and transportation activities.

Rapid urbanisation, and the widespread use of IoT-enabled devices further amplify energy needs (Batty, 2018). These factors create dynamic consumption patterns, with commercial districts peaking during the day and residential areas consuming more at night (Batty, 2018). The shift to renewable energy sources, such as solar and wind, adds complexity due to their weather-dependent and intermittent nature, requiring advanced systems to balance supply and demand in real time (Taylor et al., 2021). Effective energy monitoring is vital to identify inefficiencies, reduce waste, and achieve sustainability goals, such as those outlined in the United Nations Sustainable Development Goals (SDGs), specifically SDG 7 (Affordable and Clean Energy) and SDG 11 (Sustainable Cities and Communities) (United Nations, 2015). Without robust monitoring, smart cities risk grid instability, higher emissions, and weakened resilience, undermining efforts to build sustainable urban environments (Taylor et al., 2021). The adoption of SEDTE brings substantial advantages to smart city energy management. Through predictive analytics, it reduces energy waste by 15-25% by optimizing systems like HVAC and lighting, as well as improving grid operations. Unlike terrestrial systems, SEDTE scales cost-effectively across entire cities, making it adaptable to diverse urban settings (Ketzler et al., 2020). It also enhances decision-making by providing stakeholders with real-time insights through interactive dashboards, facilitating evidence-based policies and investments. Another key benefit is its support for renewable energy integration, as it aligns supply with demand to reduce reliance on fossil fuels, thereby strengthening grid stability (Yamagata & Seya, 2013). By minimizing inefficiencies and emissions, SEDTE contributes to urban resilience and aligns with global sustainability goals (Mohammadi & Taylor, 2017).

4.2 APPLICATIONS OF SEDTE FOR ENERGY MONITORING IN SMART CITIES

The SEDTE plays a crucial role in transform the energy monitoring process by giving real time access via digital Twin for Smart Cities. With thermal information and Satellite image over selected city area, SEDTE maps the Energy usage and detect building inefficiencies such as heat losses and poor infrastructure. It also optimizes the systems of renewable energy using solar radiation and weather data to maximize solar panel outputs or wind turbine operations for next level integration into city grids (Sharma et al., 2024). In addition, SEDTE utilizes machine learning to process satellite and ground data, including IoT sensor feeds, to forecast demand peaks and facilitate dynamic pricing or load shifting measures. It also adjusts to the environment by utilizing air quality and urban heat island information to modulate ventilation or cooling systems, improving energy efficiency while making cities more liveable (Deren et al., 2021).

As reviewed in key literature, 11 key applications of SEDTE for energy monitoring were identified as summarised in table 1.

Table 1: Applications of SEDTE for energy monitoring

Applications of SEDTE	Source of Reference
Using satellites to obtain energy monitoring data	[1], [2], [3], [4]
Facilitating real-time energy optimization and predictive analytics	[5], [6]
Increasing grid sustainability and resilience	[7], [8], [9]
Solar energy monitoring	[2], [4], [5], [6]
Facilitating dynamic load balancing and demand response	[2], [4], [5], [7]
Maximising the integration of renewable energy	[2], [6], [8], [10]
Providing an energy-efficient approach to urban planning	[4], [11], [12], [13]
Effective planning for energy systems	[2], [6], [9]
Providing electric vehicle (EV) support	[5], [6], [8]
Ensuring climate resilience and disaster preparedness	[2], [7], [9]
Reducing carbon footprint and reporting sustainability	[4], [8]

Reference: [1] Mayer & Gróf, 2021; [2] Boccalatte, 2023; [3] Tian et al., 2021; [4] Zhou et al., 2022; [5] Alola et al., 2023; [6] Gao & Huang, 2023; [7] Sghiri et al., 2025; [8] IEA, 2023; [9] Batty, 2018; [10] Taylor et al., 2021; [11] Li et al., 2020; [12] Hosseini Haghighi et al., 2023; [13] Tian et al., 2021

These applications show that SEDTE can offer a complete view of the whole city, going beyond what local systems like Building Management Systems can do. The applications showed in Table 1 in the context of energy monitoring in smart cities are described subsequently.

4.2.1 Using Satellites to Obtain Energy Monitoring Data

Satellites that carry sophisticated sensors, for instance, multispectral and hyperspectral imaging systems, gather useful environmental data which has an impact on energy use in smart cities (Mayer & Gróf, 2021). For example, satellites monitor solar conditions like solar irradiance, cloud cover, and atmospheric aerosol load directly impacting photovoltaic (PV) electricity generation at specific geographic sites (Boccalatte, 2023).

These tools are used to display the amount of solar energy available at any given time on buildings, cities, or solar farms. And satellites track weather data like wind direction and speed. Thermal imaging can also identify energy waste or building heat loss. Satellites can map out city roads and buildings using technologies like LiDAR and Synthetic Aperture Radar. These maps' details offer a clear picture of energy consumption (Tian et al., 2021). Satellite data is used to monitor energy use. S The information is transmitted to a digital twin system and analysed using machine learning and big data techniques. The digital twin integrates satellite information with information from smart meters, building management systems, and EV charging stations to provide a real-time overview of the city's energy environment (Zhou et al., 2022). According to the authors, a digital twin can illustrate the interplay between solar energy production, grid demand, and storage capacity. It considers fluctuations in sunlight as tracked by satellites (Zhou et al., 2022). This lets energy operators and urban planners predict changes in renewable energy supply and modify system operations in advance.

4.2.2 Real-Time Energy Optimization and Predictive Analytics

Satellite information used via digital twins streamlines energy usage in real time by creating an ongoing feedback loop between the physical city and virtual twin. (Alola et al., 2023). Satellites can see when solar energy drops and watch clouds. So, the digital twin can plan other ways to send out energy, like charging batteries or using backup power. The authors say that deep learning helps predict this by showing how energy is used and made. It does this by using old and new satellite data. (Alola et al., 2023). These models can identify when rare events occur, such as sudden bursts of energy usage or problems with building insulation, so early action can be taken to prevent waste. Also, digital twins use satellite data on land use to maximize where renewable energy installations are placed. (Gao & Huang, 2023). A digital twin can recommend the optimum locations for solar panels s based on a city's layout, population, and solar energy potential. This ensures that you get maximum energy without land use issues. Space needs to be considered in crowded cities because there is little land, and the energy infrastructure must be fitted into the city without causing issues.

4.2.3 Increasing Grid Sustainability and Resilience

The digital twin system backed by satellites helps keep our power grid strong by showing how energy moves through the city. Satellites can check how microgrids are working in real-time and spot problems or overloads before they affect the bigger grid. This system uses that info to run simulations for balancing energy use, making sure power stays reliable and outages are avoided. (Sghiri et al., 2025). By tracking energy consumption that produces high carbon emissions, the system helps shift towards cleaner energy, which is in line with the world's desire to limit carbon emissions. (IEA, 2023). Satellite-enabled digital twins are a good fit for smart cities, where energy systems are complicated and connected. Unlike regular monitoring systems that tend to zoom in on local data, satellites give us a wide view of the entire city, showing how energy works together and how different areas are affected by the environment. (Batty, 2018). This view helps city leaders create energy management plans that can handle local and regional needs, making the city more resilient and sustainable.

4.2.4 Solar Energy Monitoring

Satellites continuously monitor solar conditions, such as irradiance values and cloud cover, over the geographic spread of the city (Boccalatte,2023). This information is sent to the digital twin. The digital twin has a virtual representation of the city's energy system. This includes rooftop solar systems, big solar farms, and grid-connected storage devices (Zhou et al., 2022). The digital twin, as described by the authors, combines satellite images with real-time weather station and smart meter data to come up with an estimate of how much solar energy each building and zone will produce. (Zhou et al., 2022). The digital twin predicts a small drop in solar energy output and figures out how that might impact grid stability when satellite images show clouds coming in. It might also recommend increasing battery storage or adjusting energy use in less important areas. (Alola et al., 2023). Also, it can recommend increasing energy draw from battery storage or activating demand-response programs to reduce consumption in non-essential loads. Conversely, during peak irradiance times of the day, the digital twin modifies the energy supply to prioritize EV fleet charging or storing excess energy for nighttime use (Gao & Huang, 2023). The adaptive interaction between satellite data and digital twin analytics optimizes energy use, reduces losses, and enables the city to achieve its sustainability goals (United Nations, 2015).

4.2.5 Dynamic Load Balancing and Demand Response

SEDTE balances energy consumption by depicting real-time energy demand and supply (Sghiri et al., 2025). Satellites monitor weather, such as sunshine and windspeed, that impacts how much renewable energy is generated (Boccalatte, 2023). The digital twin combines this with data from smart meters to forecast busy hours and potential shortages in energy (Zhou et al., 2022). If there is an unexpected decrease in solar energy due to clouds, SEDTE can initiate software to automatically decrease energy consumption in less crucial areas such as commercial lighting or HVAC systems (Alola et al., 2023). This stabilizes the grid and enhances energy consumption at peak hours.

4.2.6 Maximizing the Integration of Renewable Energy

The varying levels of renewable energy such as sun and winds pose challenges for smart cities (Taylor et al., 2021). SEDTE utilizes satellite data to monitor weather to forecast how much energy will be generated from renewables (Boccalatte, 2023). By observing solar radiation in locations, digital twin optimizes roof-top solar systems as well as massive installations to generate maximum amounts of energy. During more energy is generated, SEDTE stores additional energy in storage units or targets high-priority needs, such as car chargers. (Gao & Huang, 2023). This application develops the efficiency of renewable energy systems and reduces reliance on backup power based on fossil fuel, aligning with the city's standards for decarbonization (IEA, 2023).

4.2.7 An Energy-Efficient Approach to Urban Planning

SEDTE helps lower energy use in buildings and other structures by spotting problems through thermal satellite images that show heat patterns. (Tian et al., 2021). Satellites have thermal sensors that can spot where heat is escaping from buildings. This helps identify spots with bad insulation or heating and cooling systems that aren't working well, as mentioned by Li et al. (2020). A digital twin uses real-time data from building management systems to give energy-saving advice, like adjusting the heating or recommending upgrades. (Zhou et al., 2022). In cities, SEDTE shows how energy is used

in different neighbourhoods. This helps urban planners spot areas that use a lot of energy and kick off projects to improve efficiency, like upgrading buildings or putting in better streetlights. (Hosseini Haghighi et al., 2023).

4.2.8 Effective Planning for Energy Systems

SEDTE is working on energy infrastructure by using land data from satellites and keeping an eye on urban building projects. Their digital twin helps identify the best spots for setting up new renewable energy sources, like solar farms or wind turbines, ensuring they generate plenty of energy while causing less impact on the land and environment. (Gao & Huang, 2023). The system can spot good roofs for solar panels or find open areas with steady winds for putting up turbines. (Boccalatte, 2023). The system can spot the best roofs for solar panels or areas with steady winds for wind turbines. It also predicts how new buildings will affect the city's energy grid, letting planners check for reliability and sustainability in the long run before they start building. (Batty, 2018).

4.2.9 Electric Vehicle (EV) Support

More electric vehicles in smart cities means we need smarter energy solutions for EV charging stations. (IEA, 2023). SEDTE makes it easy to share energy for EV charging by providing real-time info on renewable energy availability. When the sun's out, the system makes sure that energy goes to the EV chargers first before anything else, helping to make the most of clean energy. (Gao & Huang, 2023). When energy levels are low, SEDTE plans charging during off-peak hours or uses stored energy to reduce stress on the grid. (Alola et al., 2023). This helps make transportation greener and keeps the grid stable when a lot of people are using electric vehicles. (IEA, 2023).

4.2.10 Climate Resilience and Disaster Preparedness

SEDTE helps with climate resilience by spotting early signs of energy system issues caused by extreme weather. (Sghiri et al., 2025). Satellites check out weather patterns like heatwaves or storms that could affect the electricity supply or increase demand. (Boccalatte, 2023). The digital twin simulates how the city's energy system works, looking for weak spots like overloaded microgrids or broken solar panels. (Sghiri et al., 2025). By planning for options like using advanced battery storage or adjusting energy flows, SEDTE makes sure there's a steady energy supply during disasters. This is key to staying strong against climate issues. (Batty, 2018).

4.2.11 Reducing Carbon Footprint and Reporting Sustainability

SEDTE helps smart cities reach their sustainability goals by giving them real-time data on energy use and carbon output. (IEA, 2023). The digital twin keeps an eye on how well renewable energy systems are working and spots any energy waste, allowing for real-time management of the city’s carbon footprint. (Zhou et al., 2022). SEDTE makes it simple for cities to report on sustainability by providing a complete look at energy use, renewable energy sources, and cuts in emissions. This helps cities show how they are doing with global agreements like the SDGs and their own local climate plans. (United Nations, 2015).

4.3 THE PROPOSED FRAMEWORK

Based on the literature reviewed, a framework was proposed to adopt the SEDTE for energy monitoring in smart cities. As shown in Figure 1, satellites continuously monitor

solar conditions, such as irradiance levels and cloud cover, across the city's geographical area. These data are relayed to the digital twin, which maintains a virtual model of the city's energy infrastructure, including rooftop solar panels, utility-scale PV farms, and grid-connected storage systems. The digital twin integrates satellite data with real-time inputs from smart meters and weather stations to calculate expected solar energy output for each building and district. If satellite data indicate an approaching cloud cover event, the digital twin predicts a temporary drop in solar generation and simulates its impact on grid stability. It may recommend increasing energy draw from battery storage or activating demand-response programs to reduce consumption in non-critical sectors. Conversely, during periods of high solar irradiance, the digital twin optimizes energy distribution to prioritize charging EV fleets or storing excess energy for nighttime use. This dynamic interplay between satellite data and digital twin analytics ensures efficient energy utilization, reduces waste, and supports the city's sustainability goals.

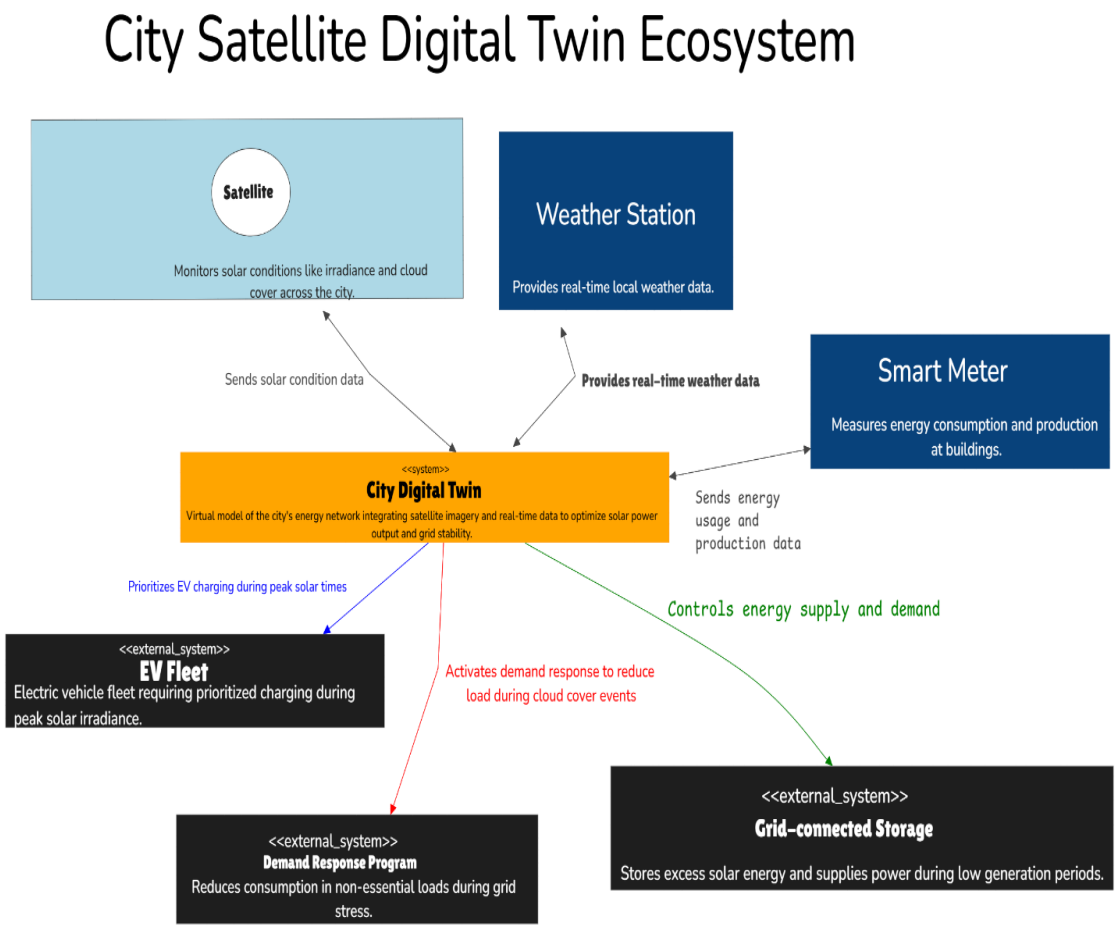

Figure 1: Proposed CITY satellite digital twin ecosystem framework (Author constructed)

In the proposed framework, sensors on satellites can capture solar irradiance, cloud cover movements, atmospheric moisture, and temperature gradients. The data received aids in forecasting solar photovoltaics (PV) energy production and estimating times during which the grid may require power or have excess supply potential. This allows smart cities to accurately forecast the need and supply. Sentinel-2 provides images pertinent to cloud cover and reflectance as well as MODIS onboard Terra/Aqua for aerosol data.

GOES and Himawari also provide real-time cloud and moisture profiles. Both satellites are equipped with global coverage and have a timely temporal resolution, making them ideal for monitoring solar potential over cities like Colombo, Kandy and Galle. Then, the data collected from satellites is integrated into a City Digital Twin, which is essentially a virtual model of the smart city integrated with GIS (Geographic Information Systems). This twin aids in monitoring the solar energy availability and forecasting its impact on the electricity grid, hence optimizing the management of the city's energy systems. Other than satellite data, weather stations and smart meters along with IoT devices installed in buildings provide essential information to fuel this digital twin. The forecasts provided by the digital twin along with other real-time data-driven decisions are sent to Building Management Systems (BMS) for automatic adjustments to energy consumption. Overall, this dual approach enhances the eco-friendliness and sustainability of cities while reducing waste. Following energy simulations, the digital twin forwards control signals to a building's BMS. These systems communicate through industry standards such as BACnet for real-time energy modification. Scheduled optimizations include pre-emptive cooling of buildings during photovoltaic downtimes, demand throttling on elevators, optimistic charging from batteries during peak solar times, and A/C sparing. This enables continuous sky feedback driven optimization of citywide energy economical building operation coordination.

5. CONCLUSIONS AND A WAY FORWARD

Energy consumption in smart cities poses a complex challenge, with urban areas accounting for high energy demand and contributing to excessive carbon emissions. Effective energy monitoring is vital to identify inefficiencies, reduce waste, and achieve sustainable development goals. Hence, monitoring energy use is vital for sustainable smart cities. Real-time monitoring has gained momentum in decision making related to building and infrastructure performance, especially for achieving energy saving and carbon emission reduction targets. Among the other technologies, satellite-enabled digital twins ecosystem powered by real-time satellite data offer a game-changing way to monitor energy use. The SEDTE revolutionizes energy monitoring by integrating real-time satellite data with digital twin technology, enabling innovative applications for smart cities. As a pathway for this newest technology adaptation, this study aimed at identifying the applications of SEDTE for energy monitoring in smart cities by reviewing key literature. Key applications of SEDTE in the context of smart city energy monitoring include data acquisition, real-time energy optimization, grid resilience, load balancing, demand responding, renewable energy integration, resilience and disaster preparedness of energy systems. The proposed framework also provides a basis for building and infrastructure professionals, policy makers towards facilitating this uphold technology adaptation in smart city development in Sri Lanka and similar contexts. However, challenges, such as data privacy concerns and high initial setup costs remain, underscoring the need for further research to ensure broader implementation. Thus, the next stage of the research will investigate the practical implementation of SEDTE in smart city development in Sri Lanka, focusing on its technological capabilities, socio-economic challenges, and strategies for successful technology adaptation.

DISASTER-RESILIENT CITIES: TEMPORAL ANALYSIS OF URBAN LAND USE LAND COVER CHANGES AND URBAN FLOODS FROM 1999 TO 2022: CASE STUDY OF COLOMBO, SRI LANKA

U. Abeysinghe[1], H.U.C.P. Hewawasam[2] and J. Manatunga[3]

ABSTRACT

This study examines the land use land cover (LULC) changes in Colombo City from 1999 to 2022, focusing on the effects of rapid urbanization on urban flood frequency and severity in the Colombo Municipal Council (CMC) area. Using high-resolution satellite imagery from Landsat 5-8, the study tracks and classifies land use over three decades, revealing significant urban expansion, a reduction in green spaces, and the loss of natural water retention zones. These changes have led to increased surface runoff, exacerbating the risk of urban floods. The research highlights that urbanization, coupled with the inadequacy of drainage infrastructure, especially in informal settlements, has contributed to the growing flood vulnerability in the city. LULC maps generated through maximum likelihood classification were validated with high accuracy, confirming the reliability of the data. Correlation analysis suggests a moderate relationship between certain land cover types (e.g., water bodies) and flood impacts, though other factors such as drainage efficiency and urban planning are more critical in determining flood risks. The study underscores the need for improved drainage systems, preservation of green spaces, and comprehensive urban planning to mitigate flood hazards. The findings emphasize the importance of integrating climate adaptation measures into urban planning, with a focus on sustainable land management and infrastructure development. The research concludes that a holistic, resilience-based approach is crucial for building a climate-resilient city capable of adapting to ongoing urbanization and climate change impacts.

Keywords: *Land Use Land Cover; Remote Sensing; Urban Floods; Urbanization.*

1. INTRODUCTION

Over the past three decades, the Colombo city area has undergone significant economic, environmental, and social changes driven by political and administrative shifts, rural-to-urban migration, and climate-induced natural disasters, which have all led to notable alterations in land use patterns (Senanayake et al., 2013; Wickramasinghe et al., 2016;).

[2] Senior Lecturer, Department of Town & Country Planning, University of Moratuwa, Sri Lanka, chamalih@uom.lk
[3] Professor, Department of Civil Engineering, University of Moratuwa, Sri Lanka, manatunge@civil.mrt.ac.lk

Particularly after the civil war (post-2014), several government-funded city remodelling initiatives, donor-funded wastewater management projects (such as the Greater Colombo Wastewater Management Plan), and infrastructure developments (like the Port City project and the Kelani Valley Highway extension) were implemented. The city remodelling program, in particular, caused significant land use transformations, including the resettlement of underserved communities into high-rise buildings, the clearance of slum areas for real estate development, the creation of new green spaces (such as pocket gardens), the establishment of tree-lined streets, and the introduction of jogging and walking paths, with many modifications to existing green spaces aimed at catering to the real estate market (Hettiarachchi, 2014). The Colombo Port City project, funded by the Chinese government, further impacted the city's land use by expanding its area. However, the economic crisis triggered by the COVID-19 pandemic and subsequent political decisions resulted in major setbacks for many of these development and beautification projects. Several were temporarily or permanently halted, and others were rolled back. (Subasinghe et al., 2021).

Rapid urbanization, a trend observed globally, has also transformed major cities in Sri Lanka, significantly altering environmental and hydrological systems. Colombo, in particular, has seen a dramatic increase in infrastructure development such as roads and buildings, reducing rainwater infiltration and amplifying surface runoff, key contributors to the rising frequency and severity of urban floods, Notable flood events in 1999, 2005, 2020, 2014, and 2022 have caused extensive disruptions, including road inundation, transportation paralysis, prolonged waterlogging, and health crises such as dengue outbreaks. In 2017, Sri Lanka ranked second in the Climate Risk Index, with Colombo highlighted as one of the most climate vulnerable cities in the developing cities. This study addresses that gap by analysing land use and land cover (LULC) changes over time in Colombo, assessing their correlation with rainfall intensity and flood impacts. Through this approach, the research offers original insights into urban planning strategies for enhancing climate resilience and sustainable development.

2. LITERATURE REVIEW

In South Asia, cities like Dhaka in Bangladesh and Mumbai in India has undergone a significant urban growth, leading to a land use changes (Hassan & Southworth., 2018). As use refers to the human activities or socio-economic functions associated with a specific land area such as residential, industrial, or agricultural use. Land cover, in contrast, denotes the physical and biological cover of the Earth's surface, such as vegetation, water, bare soil, or built-up areas (Lambin et al., 2003). Changes in the urban atmosphere, particularly the reduction of green spaces and natural drainage systems, exacerbate flood risks by reducing water infiltration and increasing surface runoff (Ahmed et al., 2013). Colombo, the commercial capital of Sri Lanka has also experienced rapid urbanization, especially since the 1990s, with the construction of new infrastructure, expansion of residential areas, and an increase in population (Dissanayake, 2021). This urban sprawl has significantly altered Colombo's natural drainage system and land cover, leading to the increase in urban flood events (Dahanayake & Wickramasinghe, 2022).

Urbanization leads to increased runoff, as more areas become impervious, with limited space for natural water absorption. This reduction in permeable surfaces results in quicker and higher-volume storm water flow, overwhelming drainage systems and causing urban floods (Jiang & Zhang., 2010). In Colombo, the combination of increased built-up areas,

encroachment on floodplains, and poorly maintained drainage systems has increased the incidence of urban floods (Dissanayake, 2021).

According to Pelling (2010), the modification of land cover, particularly the expansion of impervious surfaces such as roads, parking lots, and buildings, directly correlates with increased risk of floods in urban areas. In Colombo, the conversion of wetlands and agriculture areas to urban zones has disrupted natural water retention and flood control mechanisms (Dona, 2025). Studies have shown that flood frequency and intensity in Colombo have increased over the past few decades. In particular, Colombo faces recurrent flooding during monsoon periods (Dahanayake & Wickramasinghe, 2022). These floods are often attributed to poor urban planning, unregulated construction in flood-prone areas, and the loss of natural flood mitigation systems like wetlands (Dona, 2025). Climate adaptation measures: Studies emphasize the need for climate adaptation planning in cities to reduce the impacts of flooding. Colombo has initiated some adaptation measures, such as the expansion of its drainage system and the implementation of flood mitigation strategies, but challenges remain, particularly in informal settlements and peri-urban areas (Wagenaar et al., 2019).

Satellite imagery has been widely used for land cover classification and monitoring urban growth. Landsat imagery, for instance, provides continuous coverage since the 1970s and has been used in numerous studies on urbanization and land cover change. In Sri Lanka, remote sensing has been used to monitor urban sprawl, land use changes, and their environment impacts (Manesha et al., 2021). In urban planning, LULC change reflects the spatial and temporal dynamics of urban expansion, infrastructure development, and the conversion of natural or agricultural lands into built environments (Seto et al., 2012; Liu et al., 2010).

GIS-based flood modelling is essential for understanding how land use changes influences flood risk. Temporal analysis refers to the examination of changes in LULC over time. This involves comparing spatial data from different time periods to identify trends, rates, and patterns of changes (Herold et al., 2003). In Colombo, studies have use GIS to analyse flood-prone areas and assess the impacts of urbanization on flood vulnerability. Intense rainfall over a short period, combined with inadequate infrastructure and the reduction of green spaces, causes urban floods in urban areas. This study focus is the urban flash floods that occurred in the CMC area.

The occurrence of these disasters can be attributed to two main factors: extreme weather events resulting from climate change and poor urban planning that fails to mitigate their adverse impacts. To date, there has been no scientific analysis of urban flash floods or urban riverine floods conducted in the CMC area.

3. METHODOLOGY

This study presents a case analysis of the Colombo Municipal Council area, focusing on land use and flood risk dynamics using medium-resolution satellite imagery with a 30 m resolution, the United States Geological Survey (USGS). The images spanned a timeline from 1999 to 2022 and were captured by the Landsat 5-8 satellites. The satellite images were selected from the year of 1999, 2005, 2010, 2014 and 2022 considering the flooding events happened those respective years. We specifically downloaded Level 2 products, which are atmospherically and radio-metrically corrected to ensure high data reliability. The Level of the satellite image indicates the degree to which the raw satellite data has

been corrected and made ready for utilized. To maximize uninterrupted coverage, satellite imagery with minimal cloud cover was selected. and cloud cover were masked out using Fmask, following the approach of by Sedano et al. (2011). This process ensured the integrity of land cover classification and change detection across time. In addition to satellite based quantitative analysis, rainfall data, population density, and flood incidents recorded were assessed correlation with land use changes. Qualitative insights were gathered through referring the DesIntenver database of the Disaster Management Centre. Table 1 presents detailed metadata for each satellite images used, including sensor specifics (sensor ID refers the specific imaging instrument used on board the satellites), acquisition date, path/row (path/ row of a satellite used to identify specific geographic locations on Earth as they are captured by satellite sensors), and the percentage of land area covered by clouds.

Table 1: Details of satellite images

Year	Satellite sensor	Sensor ID	Date	Path/ Row	Land Cloud cover
1999	Landsat 5 Level 2	TM	1999-12-05	142/055	9%
2005	Landsat 7 Level 2	ETM	2005-02-05	141/055	12%
2010	Landsat 7 Level 2	ETM	2010-10-01	141/055	25%
2014	Landsat 8 Level 2	OLI-TRIS	2014-01-21	141/55	11.36%
2022	Landsat 8 Level 2	OLI-TRIS	2022-02-04	141/55	15.72%

**Time range – January 23 to March 28*

3.1 STUDY AREA

In 2023, the Western Province, including Colombo, contributed 43.7% of the national GDP, highlighting its central role in the country's economy (Central Bank of Sri Lanka[CBSL], 2024). The CMC governs the western part of Colombo, playing a key role in managing its growth and development. This highlights the strategic significance of the study area. A map of the study area us shown in Figure 1.

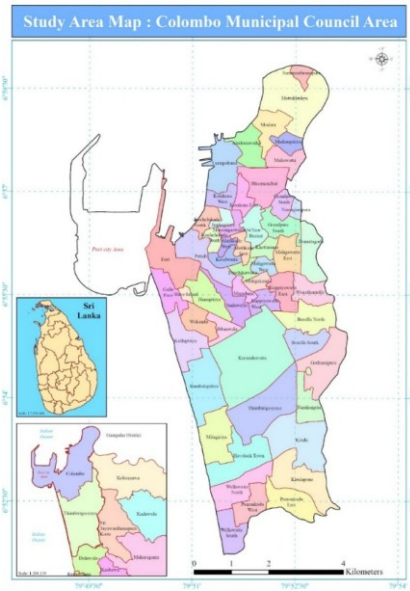

Figure 1: Colombo municipal council area

3.2 LAND USE LAND COVER CHANGE DETECTION

In this study, five LULC classes were identified within the study area: built-up areas, water bodies, barren lands, lawns & grasslands (sparse vegetation), and trees & shrubs (dense vegetation). To ensure accurate classification, we selected the highest possible number of training samples for each class, carefully considering the consistency and distribution of the satellite images over time. The land use/land cover classification was performed using the maximum likelihood classification technique, a supervised method where each image pixel is assigned to the category that most closely matches its spectral signature, corresponding to the recognized land cover types. This classification process was carried out using the ArcGIS pro 3.3 software package. To assess the accuracy of the classification, 100 random spatial points were selected for each satellite image. For historical datasets, Google Earth images (spanning from 1996 to 2023) and past land use maps available on the Google Earth platform were utilized for accuracy verification. Finally, to maintain consistency across all datasets, the classified images were resampled to a uniform spatial resolution of 30m x 30m. Following are the description of five land use classes.

- **Built-up areas**: Areas covered by man-made structures such as buildings, roads, and other infrastructure; characterized by impervious surfaces and high density.
- **Water bodies**: Includes rivers, lakes, ponds, canals, and other surface water.
- **Barren lands**: Land with little to no vegetation cover, including exposed soil, rocks, construction sites, and degraded areas.
- **Lawns and Grasslands** Areas with sparse or low-lying vegetation, including parks, fields, and recreational lawns
- **Trees and Shrubs**: Regions dominated by dense vegetation such as forests, woodlands, and plantations; typically, rich in biomass and ecological value

3.3 FLOOD IMPACT DETENTION

Flood inundation level maps, or data are not available for the study area (except for some specific locations like Kelani Valley River basin). However, the data on the area impacted (names of locations), and the number of people affected by each flood event are available from the open access DesInventar database, managed by Disaster Management Center (Disaster Management Center[DMC], 2025). These data were used as proxies for flood damage to determine the flood impact over the past 30 years in the study area, Table 2.

Table 2: Flood data used for the analysis

Data	Data type	Data source
Area impacted	Name of locations impacted	DesInventar Database
Number of people impacted	Number	DesInventar Database

3.4 CORRELATION ANALYSIS OF LAND USE LAND COVER CHANGES AND FLOODING

Correlation analysis was performed using Minitab version 20.2 to explore the relationships between key variables in the study. Specifically, the analysis aimed to identify the nature and direction of the relationships between flood locations, the number of people affected by floods, and the percentage of land use change (measured as the temporal variation in land use classes). Through this analysis, we sought to determine

whether the relationships were positive or negative, providing insights into how these factors interrelate. Additionally, the strength of these relationships was evaluated, allowing us to assess whether the associations between the variables were strong or weak. By conducting this correlation analysis, we were able to gain a deeper understanding of the dynamics between flooding events and changes in land use within the study area.

4. RESULTS AND DISCUSSION

4.1 LAND USE LAND COVER MAPS AND ACCURACY ASSESSMENT

The LULC maps were developed for 1999, 2005, 2010, 2014, and 2022 year, are presented in Figure 2. The maps clearly indicate the significant land use changes the CMC area has undergone during past three decades.

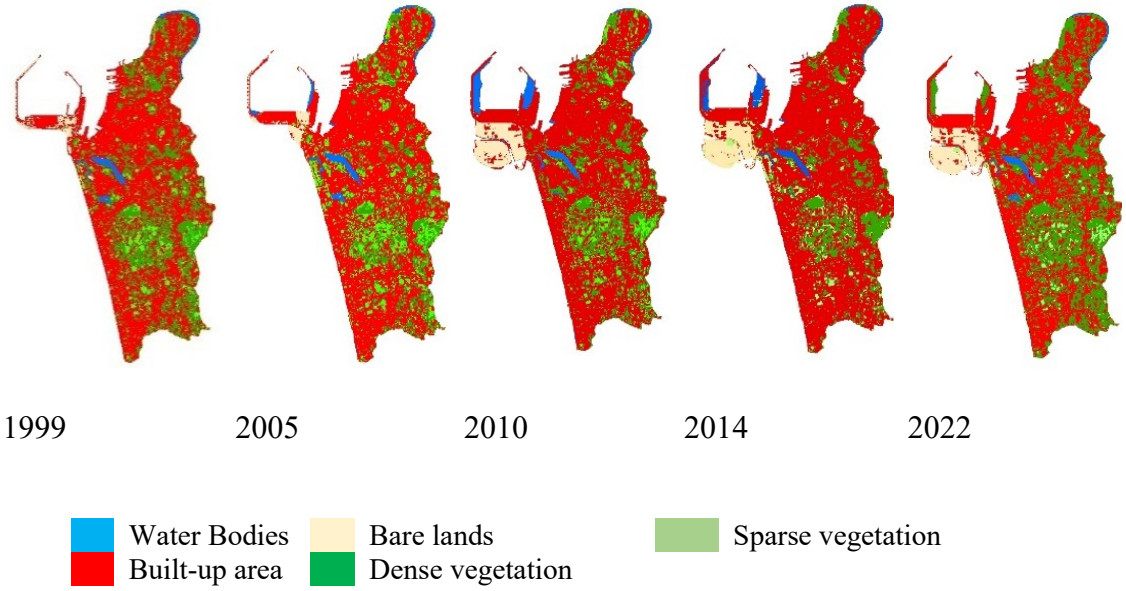

Figure 2: LULC Maps of 1999, 2005, 2010, 2014, and 2022

Table 3 presents the user accuracy, which is the is the probability that a pixel classified into a certain category on the map actually represents that category on the ground, and kappa coefficient which quantifies the agreement between the classified map and reference (ground truth) data values for each LULC map generated.

Table 3: Accuracy assessment of Land Use Land Cover maps

Year	U_Accuracy	Kappa
2022	0.930	0.855
2014	0.910	0.827
2010	0.930	0.867
2005	0.940	0.885
1999	0.910	0.817

The land use areas under five different land use categories, water bodies, built-up areas, bare lands, dense vegetation, and sparse vegetation were presented in Table 4. There is a

significant increase of the urban greenery in the CMC area due to the city remodelling programs undertaken during the past war period (Abeysinghe et al., 2024).

Table 4:Land use areas under different land use categories

Year	Water bodies	Built up area	Bare lands	Dense vegetation	Sparse vegetation
2022	2.80	72.44	5.21	14.26	5.28
2014	1.43	56.65	5.18	33.20	3.54
2010	3.05	67.68	5.27	17.00	6.99
2005	2.36	67.61	1.81	14.59	13.62
1999	1.78	63.32	2.02	26.35	6.51

4.2 TEMPORAL ANALYSIS OF URBAN FLOODS IN COLOMBO MUNICIPAL COUNCIL AREA

During the period between 1999 and 2022, the CMC area experienced several major flood events, each of which had significant impacts on the local population. As shown in Figure 3, the number of people affected by floods has gradually increased over the years, with a noticeable rise in the frequency of these events. The graph provides an insightful analysis of flood-affected individuals in the CMC area, revealing an upward trend both in the number of people affected and in the frequency of flood occurrences. This increase underscores the growing vulnerability of the city to flooding, particularly urban floods, which have become a recurrent issue in the region. The map provides a detailed view of where flood events occur most frequently within the CMC area. It shows that the flood risk is not evenly distributed across the city, and only some parts are in high risk.

The most flood prone areas in Colombo include neighbourhood such as Grandpass South and North, Maradana, Nawagampura, and several others that have been consistently affected by flood events. There areas experienced severe flooding during major events in 1999, 2005, 2010, 2014, and 2022. Key contributing factors include heavy rainfall, inadequate drainage systems, and rapid urbanization. Understanding these patterns is essential for developing effective flood management strategies and enhancing the city's resilience.

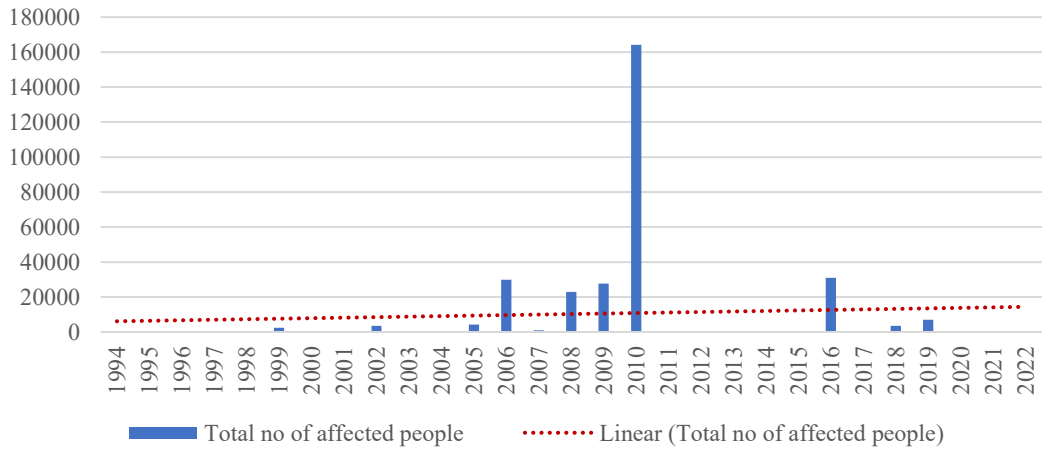

Figure 3: Flood affected people over 1994-2022

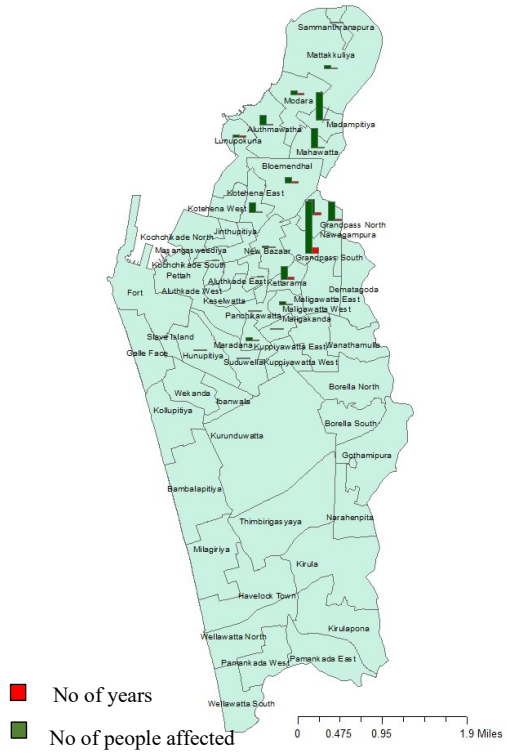

Figure 4:Flood events and severity in different locations

4.2.1 Correlation Analysis of the Land Use Changes and Urban Flood Impact

The correlation of the different land use land cover change and the number of flood affected people was assessed using minitab 20.0 software. The correlation coefficient, R-square, and the *p-value* is presented in the Table 5.

Table 5: Correlation of land use land cover change and the number of flood affected people

Land use type	Correlation coefficient	R-Square (%)	p-value
		No of people affected	
Water bodies	0.522	27.3	0.367
Built-up area	0.063	0.4	0.920
Bare lands	0.505	25.5	0.386
Dense vegetation	-0.142	2.0	0.820
Sparse vegetation	-0.117	1.4	0.851

The correlation coefficient between the extent of water bodies and the no of people affected is moderately positive, r-square is 27.3 % suggest that water bodies have modest predictive influence on the number of people affected and the p value is not statistically significant. The correlation coefficient of the built-up area extent and the number of people affected shows a very weak positive correlation, and the p-value is very high, suggesting that there is no significant relationship. There is a moderately positive relationship between bare lands and the number of flood affected people, and p-value is not statistically significant. The negative correlation suggests that areas with dense

vegetation tend to experience fewer people being affected by flooding, likely because vegetation helps reduce runoff and prevents soil erosion. However, the correlation is weak, indicating that vegetation alone does not have a significant influence on the number of people affected. Dense vegetation explains only 2% of the variation in the number of people affected, confirming that dense vegetation has minimal predictive power in this scenario. The relationship between dense vegetation and the number of people affected is not statistically significant, indicating that vegetation in this case does not have a measurable impact on flood outcomes. Similar to dense vegetation, sparse vegetation shows a very weak negative correlation with the number of people affected. Sparse vegetation accounts for only 1.4% of the variation in the number of people affected, further suggesting that vegetation density (whether dense or sparse) is not a major driver of flood impacts in this case. The p-value is very high, reinforcing the idea that sparse vegetation has no statistically significant impact on the number of people affected by flooding.

4.2.2 Correlation Analysis of the Rainfall Intensity and the Flood Impact

The correlation of the intensity of the rainfall (rainfall within 24 hr) and the number of flood affected people were assessed using minitab 20.2 software. The rainfall data of the selected urban flood events were obtained from the Department of Meteorology. The correlation analysis was conducted for the rainfall intensity and the number of people affected during above mentioned flood events were presented in Table 6.

Table 6: Correlation between the rainfall intensity and the number of people affected

Variable	Correlation coefficient	R-Square (%)	p-value
		No of people affected	
Rainfall intensity	-0.342	32.4	0.317

The correlation coefficient of -0.342 indicates a weak negative relationship between rainfall intensity and the number of people affected. This means that, as rainfall intensity increases, the number of people affected tends to slightly decrease. However, the relationship is weak, and the strength of this correlation is not very strong. The p-value of 0.3174 is greater than 0.05, meaning the correlation is not statistically significant. This suggests that the weak negative correlation observed between rainfall intensity and the number of people affected is likely due to random chance. Therefore, we cannot conclude that rainfall intensity significantly influences the number of people affected.

5. CONCLUSION

This study offers a detailed examination of the LULC changes in Colombo City from 1993 to 2022, using advanced remote sensing techniques and rigorous analytical methods. The research focused on how rapid urbanization, driven by socio-political factors and infrastructure developments, has influenced the frequency and severity of urban floods in the CMC area. The study leveraged high-resolution satellite imagery from Landsat 5-8 to track and classify land use over three decades, providing an in-depth temporal perspective on the transformation of the city's landscape.

The key findings of this research highlight that Colombo has experienced significant land use changes, particularly an expansion of built-up areas and a reduction in green spaces

and natural water retention areas. These changes have directly impacted the city's hydrological dynamics, with the increased urbanization contributing to higher levels of impervious surfaces, which reduce natural water absorption and lead to increased surface runoff. This alteration in land cover has exacerbated the risk of urban floods, as the city's drainage infrastructure, particularly in informal settlements, has struggled to keep up with the rising demand and urban sprawl. Moreover, the loss of wetlands and other natural flood mitigation systems has further compounded the issue.

The accuracy of the LULC maps generated through the maximum likelihood classification technique was assessed through extensive validation processes. The high user accuracy and kappa values (e.g., 0.855 in 2022) confirm the reliability and robustness of the dataset, which serves as a valuable tool for urban planners and policymakers seeking to address the city's growing vulnerability to urban floods.

Additionally, the correlation analysis provided further insights into the complex relationship between land use changes and flood impacts. As stated Sohn et al., (2020), the modification of land cover, particularly the expansion of impervious surfaces such as roads, parking lots, and buildings, directly correlates with increased risk of urban floods in urban areas. This study found that the relationship between the rainfall intensity, and LULC change, and flood impact are more complex, and influenced by multiple factors. Water bodies and barren lands showed moderate positive correlations with the number of flood-affected people, while dense vegetation showed a weak negative correlation, suggesting ta possible mitigating effect. However, these correlations were not statistically significant. The findings suggest that factors like drainage infrastructure and urban planning play a more critical role in flood outcomes than LULC alone. Additionally, the weak negative correlation between rainfall intensity and affected individuals indicates that flood severity depends more on urban response than rainfall volume alone.

Despite efforts to expand drainage systems, problems continue, especially in informal settlements that are highly vulnerable to flooding. While green spaces and water bodies provide some mitigations, they cannot fully counter the risks from unregulated construction and poorly maintained drainage. This highlights the limitations of current flood control efforts. The study emphasizes the need for integrated urban planning that combines flood management with sustainable land use and environmental practices.

This research reinforces the need for continuous monitoring of LULC changes in Colombo and highlights the importance of integrating climate adaptation measures into urban planning processes. Policymakers should prioritize sustainable land management practices, such as preserving natural flood buffers, enhancing green spaces, and improving the capacity of drainage infrastructure. Furthermore, the findings underscore the importance of adopting a holistic approach to urban resilience—one that combines infrastructure improvements with community engagement, disaster preparedness, and climate-conscious governance.

Urban flooding is a significant issue in the CMC area. However, changes in LULC patterns, along with rainfall intensity, are just two factors that exacerbate the impact of these floods. The relationship between urban floods, rainfall intensity, and LULC changes is more complex, with several additional factors that must be taken into account. These include the drainage network of the area, soil water infiltration capacity, and overall hydrological patterns, among others. Study suggest that further research is needed to explore these factors in greater detail.

In conclusion, this study provides valuable insights into the spatial-temporal dynamics of Colombo's urbanization and flood risks and offers important recommendations for building a climate-resilient city. The evidence suggests that while urbanization is inevitable, its negative impacts can be mitigated through informed decision-making, adaptive urban planning, and the integration of nature-based solutions to enhance flood resilience. As Colombo continues to evolve, it is crucial to balance development with sustainable environmental practices to ensure that future generations can live and thrive in a safer, more resilient city.

EARLY COMMISSIONING OF MEP WORKS FOR BETTER BUILDING PERFORMANCE

Chathuranga Jayasinghe[1], Sachie Gunatilake[2] and Dasuni Kodituwakku[3]

ABSTRACT

Mechanical, Electrical and Plumbing (MEP) systems play a pivotal role in functionality of high-rise building (HRB) projects. Building commissioning helps to ensure that the building systems operate as intended, confirming their compliance with design and owner's requirements. Studies have highlighted the benefits of MEP commissioning from initial stages especially in HRB projects. However, due to a variety of reasons, MEP commissioning is frequently restricted to achieving "practical completion" at the project handover stage, Thus, the maximum benefits of this approach is not experienced due to the absence of commissioning activities in the initial building stages. This study aims to investigate the building commissioning activities for MEP works during the pre-design and design project stages of HRB projects in Sri Lanka. Firstly, the commissioning activities that should be carried out during the stages were identified from the literature. Then, 20 semi-structured interviews were conducted to explore their application in Sri Lankan HRB projects. Findings revealed that most activities were not conducted or conducted in an inadequate manner during the pre-design and design stages. Activities such as appointment of a third-party commissioning authority, establishment of commissioning scope, and preparation of commissioning plan were especially given poor attention. Lack of standards specialised to Sri Lanka, cost and time constraints, and unavailability of technology and experts were found as the major challenges for poor implementation of initial commissioning procedures. The findings provide a useful first step towards enhancing the early implementation of building commissioning procedures for MEP works in the local context.

Keywords: *Building commissioning; High- rise buildings; MEP systems; Sri Lanka.*

1. INTRODUCTION

The Mechanical, Electrical, and Plumbing (MEP) systems function as the lifeblood of the buildings (Khan & Shaari, 2023). These MEP systems consist of plumbing works, Heating, Ventilation, and Air-Conditioning (HVAC), electrical, energy conservation and elevator maintenance and other related installations and comprise complex processes, activities, and resources. Once the operational stage begins, these services are essential for the proper functioning of a building (Han et al., 2022) and for ensuring the expected comfort and safety for occupants. MEP works may constitute up to 40 to 60% of total project costs. Moreover, the rework rate for the MEP installations is also high approaching 20% (Wu et al., 2022). In high rise buildings (HRBs), the percentage of MEP work is around 26% of the total construction work (Riley et al., 2005; Wang & Leite, 2016). Accordingly, Crowe et al. (2020) have highlighted the requirement of a systematic

[1] Department of Building Economics, University of Moratuwa, isurujana981028i@gmail.com
[2] Senior Lecturer, Department of Building Economics, University of Moratuwa, sachieg@uom.lk
[3] Lecturer, Department of Building Economics, University of Moratuwa, Sri Lanka, ldasuni@uom.lk

approach for involving MEP works in HRBs that consider user requirements and bring more value through business-building alignment.

As described by Crowe et al. (2020), building commissioning is aimed at improving the execution of both new and existing construction endeavours. It attempts to verify the proper installation, testing, and functioning of the building systems according to their intended design (Coyner & Kramer, 2017). In addition, Vejrum (2023) stated that this is a comprehensive approach which centres on confirming and recording that all systems and components authorised are systematically mapped out, conceived, set up, evaluated, and utilized to fulfil the owner's project requirements for a novel structure and substantial refurbishments. Accordingly, commissioning provides remedial actions for minimizing reworks, which has become a significant challenge within the construction industry since they lead to inefficiency and unnecessary resource depletion while impacting both the design and construction stages of projects (Harker, 2018). Thus, commissioning can be identified as a tool that is essential for ensuring project cost, quality, and timeline achievements.

Several studies have highlighted the benefits of MEP commissioning from initial project stages especially in HRB projects. For example, building commissioning during start-up is advantageous for resolving initial issues and ensuring that HRBs operate as intended by bringing systems to full functionality (Caglayan et al., 2022). Furthermore, this proactive approach aims to swiftly address potential design-related issues, minimising the need for later reworks. However, due to time and budget constraints, commissioning is frequently restricted to achieving "practical completion", and the objectives may remain unrealized (Noye et al., 2015). This lack of attention to building commissioning in the early project stages can lead to several drawbacks, such as reworks, incorrect operation, inadequate documentation, missing equipment, and untrained operators, hampering efficiency and long-term functionality (Doloi, 2014). In addition, neglecting commissioning for MEP works from the planning stage can also result in schedule delays, uncontrolled delivery schedules, and increased construction costs, as well as improper fits during installation due to as-built deviations between structures and the MEP layout (Wang et al., 2016). Despite this, still building commissioning is often viewed as an activity or a set of activities to be conducted at project handover. This view is particularly prevalent in the local context as evidenced in the works of authors such as Pilanawithana and Sandanayake (2016) and Samarasinghe et al. (2016). Hence, this study aims to investigate the building commissioning activities for MEP works during the early project stages of HRB projects, which in turn is essential to ensure long-term functionality and efficient building performance. The paper first presents an overview of MEP works in HRBs and the concept of building commissioning. Then, the research methodology is detailed. The findings on the current approach to commissioning in the Sri Lankan context are briefly discussed next. Thereafter, the findings on the application of building commissioning activities during the predesign and design stages and the challenges for implementing the same are discussed. Finally, the conclusions and the implications of the research findings are presented.

2. OVERVIEW OF MEP WORKS IN HIGH-RISE BUILDINGS

MEP systems in HRBs include essential sub-systems such as electrical distribution system, heating, ventilation and air-conditioning (HVAC), potable water supply and distribution, sanitary drainage and sewage systems, fire protection systems and elevators and escalators (Han et al., 2022; Hu et al., 2023). These services are significant for the basic functioning and the quality of life of occupants. For example, MEP services ensure the efficient distribution of power, water, and climate control throughout the building (Jawad et al., 2021). Without the proper functioning of these MEP systems, HRBs would be uninhabitable, impractical, and unsustainable (Monsberger, 2019). Hence, according to Lee and Ahn (2018), MEP systems can be considered as the lifeblood of HRB structures.

3. BUILDING COMMISSIONING

According to the American Society of Heating, Refrigerating and Air-Conditioning Engineers (ASHRAE, 2019), building commissioning is a "quality-oriented process for achieving, verifying, and documenting that the performance of facilities, systems, and assemblies meets defined objectives and criteria". Thus, commissioning helps to ensure that building systems operate as intended, confirming their compliance with design and owner's requirements, and documenting the process.

According to Doloi (2014), building commissioning should begin during the concept design phase, where project goals and performance criteria was established and ensure that MEP systems are designed to meet specific standards and expectations. Similarly, Monsberger (2019) highlights that to obtain maximum benefits, commissioning must begin in initial stages such as strategic definition, concept design and technical design where the initial MEP designs are outlined in modern construction projects. Thus, several existing literatures (Coyner & Kramer, 2017; Frye et al., 2002; Su & Thomson, 2016) have categorised building commissioning aspects under four main stages, including pre-design, design, construction, and post-construction. These four main stages can be defined using the work stages of the RIBA Plan of Work 2020 as given in Table 1.

Table 1: Categorisation of commissioning stages in existing literature according to the stages of RIBA plan of work 2020

Commissioning stages in existing literature	Relevant stages of RIBA plan of work 2020
Pre-design stage	Strategic Definition stage
	Preparation and Brief stage
Design stage	Concept Design, and
	Spatial Coordination
	Technical Design stage
Construction stage	Manufacturing and Construction stage
Post-construction stage	Hand over
	In-Use stage

Lack of building commissioning for MEP works in the early design stages can lead to several challenges. Eon et al. (2020) identified the drawbacks including discrepancies between the as-designed and as-built energy performance of the building often due to a lack of knowledge and communication between stakeholders. Inadequate consideration of requirements in the early design stages can also result in energy performance gaps in non-domestic buildings, impacting the overall efficiency and sustainability of the HRBs (Thompson et al., 2022). Thus, this paper particularly focuses on the pre-design and design stage commissioning activities for MEP works particularly in the context of Sri Lankan HRBs.

4. RESEARCH METHODOLOGY

This study aimed to investigate the building commissioning activities for MEP works during the early project stages of HRB projects and the challenges associated with the same. Through the literature survey, the commissioning activities that should be conducted in the pre-design and design stages were identified. The study used a qualitative approach as it allowed to gain a deeper understanding about the applicability of these activities in commissioning MEP systems in Sri Lankan HRB projects and challenges in doing the same. Semi-structured interviews were chosen as the data collection method because they offer the flexibility to gather additional pertinent information during data collection without being limited to a structured questionnaire. Interviews were conducted with twenty (20) experts who were passionate, well experienced and have the knowledge regarding the commissioning for MEP systems in the Sri Lankan context as evidenced by their years of experience in the industry and the number of MEP projects involved (refer to Table 2). An interview guideline was prepared based on the literature review findings to guide the interview process. The interviewees were selected using purposive sampling with the aim of covering all perspectives including client, contactor, and consultants. The interviews lasted between 40-55 minutes each and were conducted either in-person or online, based on the availability of the respondents. The number of interviews conducted was limited to 20 due to data saturation. The profile of the selected interviewees is given in Table 2.

Table 2: Profile of interviewees

Respondent	Designation	Experience in MEP context (Years)	No. of MEP projects involved	Current perspective	Specialized systems
E1	Senior consultant	44	100+	Consultant	HVAC systems
E2	Deputy General Manager - Design	30	30+	Contractor	Mechanical, Plumbing system
E3	MEP Manager - Design, Estimation and Quality Assurance	28	25+	Contractor	Overall MEP
E4	Maintenance Engineer	25	10	Client	Overall MEP
E5	Senior MEP Manager, Consultant	20	15	Client	Overall MEP

Respondent	Designation	Experience in MEP context (Years)	No. of MEP projects involved	Current perspective	Specialized systems
E6	MEP Site Manager	19	46	Contractor	Overall MEP
